20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

The relationship between military service and post-service earnings was analyzed using the 1976 data of the National Longitudinal Survey of Young Men (14 to 24 years of age in 1966). The sample was broken down by race and veteran status. When earning attributes were examined it was found black veterans on average were socio-economically better off than black non-veterans, while the reverse was true for whites. This era, which included

1

#20 - ABSTRACT - (CONTINUED)

draftees, lottery selectees, and volunteers, failed to produce a military which was representative of society. The post-service earnings analysis indicates that the effect of military service on subsequent civilian income was negative. This was particularly true for those veterans who failed to use the military's in-service or post-service opportunities to further their general level of education or undertake vocational training. In sum, a term in the military has a more positive earnings effect than civilian unemployment, but a more negative earnings effect than civilian employment.

A major recommendation is that programs withdrawing members from the civilian sector for extended periods need to compensate adequately those members either during or after service.

ABSTRACT

The relationship between military service and post-service earnings was analyzed using the 1976 data of the National Longitudinal Survey of Young Men (14 to 24 years of age in 1966). The sample was broken down by race and veteran status. When earning attributes were examined it was found black veterans on average were socio-economically better off than black non-veterans, while the reverse was true for whites. This era, which included draftees, lottery selectees, and volunteers, failed to produce a military which was representative of society. The post-service earnings analysis indicates that the effect of military service on subsequent civilian income was negative. This was particularly true for those veterans who failed to use the military's in-service or post-service opportunities to further their general level of education or undertake vocational training. In sum, a term in the military has a more positive earnings effect than civilian unemployment, but a more negative earnings effect than civilian employment.

A major recommendation is that programs withdrawing members from the civilian sector for extended periods need to compensate adequately those members either during or after service.

I. INTRODUCTION

A. INTRODUCTION

The Department of Defense (DoD) is the single largest employer of youth in America. With the inception of the All Volunteer Force (AVF) in 1973, the military has been required to compete in the labor market to recruit approximately 350,000 young men and women each year to meet its authorized strength. Approximately ninety percent of those young men and women will be between 17 and 21 years of age. This is a critical period in the development of their personal and vocational goals.

In excess of ninety percent of these young men and women will attend a formal course of instruction in the skills required for their specialized military occupation [Gay, 1978]. This will be followed by intensive on-the-job training and possibly advanced training at a later date. Except for the public educational system, the military training organization is the largest training system in America. In 1977 the Congressional Budget Office estimated that training costs at formal military training centers and academic institutions were at least $6.25 billion. In addition, it was estimated that at any one time 18 percent of all active duty military personnel are involved in the training system as students, instructors, or supporting staff. This estimate did not include on-the-job and unit training activities. For this

reason the armed forces have continually emphasized their
ability to provide valuable job training and work experi-
ence to the potential recruit.

Clark and Sloan (1964) indicate that 85 percent of all
enlisted personnel job specialities have a direct civilian
counterpart. Also, 60 percent of all military training and
education had direct application to civilian life. Weinstein
(1967) found approximately 50 percent of all enlisted job
specialities fall into the skilled category. Thus, it is
not surprising why many young people see the military as an
attractive method of gaining work skills and experience.

Approximately 78 percent [Binkin, M., and Kyriakopoulos,
1979], of enlistees do not complete more than one tour of
duty. Therefore, the returns in subsequent civilian employ-
ment that accrue to an individual as a result of his mili-
tary service is of considerable interest to both the potential
enlistee and the military recruiter. Clearly, if there were
lifetime civilian earning benefits to be gained through mili-
tary service, recruitment would be enhanced.

B. PROBLEM

Research to estimate the benefits of military service began
in the late sixties as part of the debate over conscription
versus the All Volunteer Force. Recent impetus for further
research in the area has been a result of calls for the rein-
troduction of the draft or national service to raise military
manpower. Demographic and economic trends for the 1980's
indicate that the military may have difficulty in recruiting

suitable young males. As the supply of males 17 to 21 years of age reduces, substantial increases in wages and incentives will be required for the military to remain competitive and obtain the quality and quantity of young people needed.

Besides the political and emotional reactions that arise with consideration of conscription or national service, there are some very real economic and social issues of "who serves when all don't" and the "tax or benefit to those who serve". Unfortunately, there have been no conclusive findings on the earnings effect of military service due to the variety of data sources and methodologies employed. Many of the studies of the sixties were conducted by economists, Oi (1967), Renshaw (1960), Hansen and Weisbrod (1967), who found that the effect of military service on earnings was negative. In contrast, later studies by Little and Fredland (1979), Martindale and Poston (1979) and Lapreato and Poston (1977) found socio-economic benefits accruing to veterans. The benefits were especially attributed to minority veterans who had used their military training to improve their socio-economic status. Most of these studies have been criticized on the fact that they were short term in nature and did not adequately address life cycle benefits. If military training does provide post service premiums, this knowledge could be utilized to attract enlistees on the basis that military service is an alternative method of investing in human capital, in a manner similar to education or specific vocational training. Similarly, policies like "Project 100,000" could be supported and

justified on socio-economic grounds that the military is an appropriate employer for developing civilian employment enhancing skills for less employment qualified youths.

Human capital theory is the basis for this thesis and is briefly reviewed in the following chapter. The major studies concerning the economic benefits in post service employment are also described in the next chapter. Using these studies as a framework, three hypotheses were developed and tested.

The first hypothesis questioned whether earnings related factors possessed by veterans were similar to the population from which they were drawn. The second and third hypotheses attempt to identify earning returns to veterans, based on these factors and specific aspects of military service. If military training and work experience is to be attributed as a means of accumulating human capital, then those who undertook military service should show positive earnings premiums over individuals with similar attributes who chose not to enter the military. Thus, the presence or absence of an earnings premium will be used to judge th value of military service in subsequent civilian employment.

This thesis will present a review of current studies undertaken in this area in Chapter II. Chapter III details the methodology, data base and the sample selection process used in the thesis. After Chpater III are the three analytical chapters. Chapter IV tests the first hypothesis and is a detailed examination of the sample when disaggregated by race and veteran status. Following this in Chapter V is the multiple

regression analysis to ascertain the economic returns to
veteran status. Finally Chapter VI examines the different
patterns of military participation in influencing port
service earnings. The last chapter gives the summary, con-
clusions and recommendations of the thesis.

II. REVIEW OF BACKGROUND STUDIES

A. INTRODUCTION

The first part of this chapter reviews human capital theory. Most of the recent and initial developments in this field can be specifically attributed to the contributions made by Schultz (1963), Mincer (1974), and Becker (1975). Following the discussion of human capital theory, a number of current studies on socio-economic returns to veterans are examined to idtify their purpose, methodology, and results.

B. HUMAN CAPITAL THEORY

Generally, the word "capital" connotes the ability to use accumulated stock of natural or man-made goods for the further production of goods. Human capital refers to the levels of skills and training possessed by individuals [Fleisher and Kniesnen, 1980]. With the realization that the formation of human capital · important both to individual and societal economic growth and stability, economists, sociologists, educators and psychologists have increasingly devoted their talents to the broad range of human resource problems. This research has been accompanied by increasingly large governmental expenditures in such areas as education, health, welfare, migration, and manpower programs. The relationship between expenditure on human capital for increased national product and increased national wealth is thus well established.

Becker's (1975) analysis of costs and benefits or returns to investment in human capital is now a widely used method of studying human capital formation. He uses the human capital approach not only to help explain differences in earnings over time and among geographic areas, but also among individuals within an area. Thus he provides a powerful link between earnings ability and the incentive to invest in human capital.
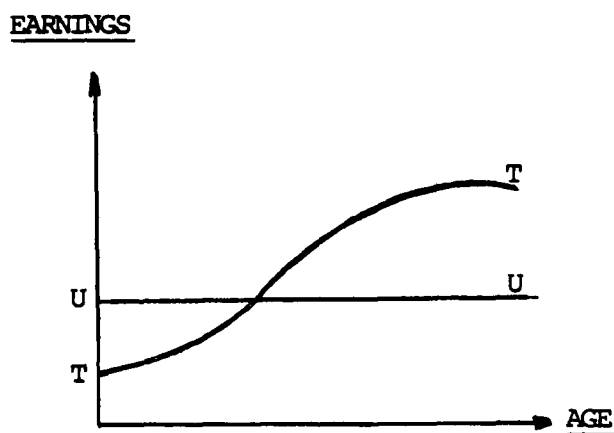

EARNINGS

Figure 1:   Relation of Earning to Age

From Figure 1, the horizontal line UU indicates earnings of untrained individuals regardless of age. The TT curve shows earnings of individuals who are trained. In this case, trained persons receive lower earnings initially because the costs of training are being paid.

Costs for formal educational programs may be actual costs or opportunity costs. For on-the-job training (OJT), costs are measured indirectly by the lower productivity of the worker during the learning period and the cost of supervision

18

by his superiors. Higher earnings at a later stage are possible with increased experience and training gathered over time (age). Thus returns to training are found to accrue to the individual. Investments in human capital create an increasing differential of the age-income structure of more qualified manpower vis-a-vis less qualified personnel.

In particular, Becker distinguished between general training which is useful and readily transferable to many firms, and specific training which tends to increase productivity more exclusively in the particular firm or organization providing the training. Consequently, the cost of general training would be borne by the individual receiving the training, while specific training would be paid for by the firm. Most training is neither completely specific nor completely general. To the military recruit who is not intent on being a careerist, general training is probably more important than specific training. General training will be more transferable to the civilian sector, whereas specific military skills will have little value in the civilian labor market.

Becker's analysis of Human Capital Theory offers a unified explanation to the following phenomena:

1. Earnings typically increase with age at a decreasing rate. The rate of increase is positively related to the level of skill.

2. Unemployment rates are inversely related to the level of skill.

3. The distribution of income is positively skewed, especially for professional and skilled workers.

4. Abler persons receive more education and training than others.

These aspects are important and can be related to studies that examine the effects of military training and work experience on post service employment and earnings. In particular, if the above basic points of human capital theory are accepted, then age, weeks of employment, education, and training should result in positive returns for additional units possessed of each factor.

In summary, human capital theory is the study of individual wage determination. The model proposes that the wage paid to each worker is determined by the education and skill possessed by that worker which enhances his productivity. This means that the worker who has obtained specific training skills or even general training, through on-the-job training (OJT), and work experience, should receive a wage premium above those of less qualified workers.

C. HUMAN CAPITAL INVESTMENT BY MILITARY SERVICE

The military not only gives specific skill training in many jobs that have a direct civilian counterpart, but is also said to promote desirable, and valuable job qualities [Browning et al., 1973]. Qualities often attributed to military training are: the development of positive attitudes, self-discipline, fitness, teamwork, loyalty, safety and security consciousness, geographic mobility, initiative, independence, and confidence. All of these qualities are generally recognized

as enhancing productivity and employability. In addition to military experience promoting these environmental work factors, service members are required to meet entrance criteria. These physiological and psychological tests and the requirement of a criminal free record provide a screening mechanism indicating to employers that veterans are "quality" personnel.

If the military does develop these qualities and provides a certification standard, human capital theory would indicate that veterans would receive a wage premium in subsequent civilian employment. Thus, military service could be established as an alternative method of investing in human capital because the training and work experience obtained were not only readily transferable to the civilian sector, but were recognized by the wage premium employers were willing to pay.

D. OVERVIEW OF PAST STUDIES

Most of the early studies by economists, Oi (1967), Renshaw (1960), Hansen and Weisbrod (1967) have concluded that the economic effect of military service has been detrimental to enlistees. These studies were based on earning differences (the opportunity cost or loss) sustained by individuals while in the military. Given the low wages being paid to the military during the draft period, the results indicated there was a "conscription tax" placed on those who served.

The best possible indication as to the cost and benefits of military service would be to randomly assign individuals

to groups then compare earnings before, during, and after military service to develop a life time earnings path. Unfortunately, longitudinal earnings data on randomly assigned groups are not available. Although some of the studies reviewed do attempt to reduce this deficiency by using longitudinal multivariate analysis, most studies are cross-sectional in nature.

E. STUDIES REVIEWED

1. Cutright (1972)

Cutright states there are five possible positive effects of military service that may contribute to post service earnings:

a. The geographic military effect. Cutright proposed veterans reared in the south were probably more likely to leave this low wage area, as a result of their military service.

b. The credential effect. An honorable discharge may serve as an indicator to employers that veterans were reliable, had work experience, and possessed the minimum military service educational standards.

c. In-service vocational training. This may provide some men with skills for civilian jobs which they may not otherwise have obtained.

d. Post-service training. The G.I. Bill opportunities may give veterans an advantage in the civilian market which may not have been possible had they not undertaken military service.

e. Psychological benefits. All the intangible attributes of military service. For example, the belief that "the Army builds men."

Negative effects identified by Cutright, other than the physical and psychological effects of war, were low military

earnings and delays imposed by military service in the completion of education and training.

Cutright's sample only contained men who were draftees and non-veterans born between 1927 and 1934. Calculating average incomes earned in 1958 and 1964, while statistically controlling for intelligence using Armed Forces Qualification Test Scores, he compared the veteran and non-veteran groups. The 1958 income was approximately three to four years after service discharge while the 1964 figures gave incomes nine to ten years after active service. His conclusions were that earnings of veterans are not higher than the earnings of comparable non-veterans. In particular, he concluded that any military or comparable civilian program that removed men from the labor market for an extended period of time would depress post-program earnings.

2. Norrblom (1976)

This study reported the effects of formal military vocational training and on-the-job training acquired while working in a military speciality. The results indicated that formal military vocational training had a significant upward impact on wages of individuals who entered a related civilian occupation. However, Norrblom found that on-the-job training in military specialities that were parallel to current civilian occupations of veterans had no significant impact on post service earnings. Additionally Norrblom found that returns to on-the-job training acquired in the civilian sector were

significantly larger than previously thought. Unfortunately, her study only included veterans, so it was not possible to determine any net advantages accruing to veterans over non-veterans as a result of military training.

3. University of Texas Studies

Three studies by Browning, Lapreato and Poston (1973), Lapreato and Poston (1977) and Martindale and Poston (1979), indicate that military service may provide a "bridging environment" for minority groups that result in socio-economic advantages in the post service period. These studies propose that the military not only provides opportunities for occupational training, education, and geographic mobility, but also assists individuals to obtain personal independence, confidence, and the ability to experience bureaucratic structures. Military experience is said to be a critical factor that enable minority veterans to obtain better paid civilian jobs in the post service period.

While all studies used similar methodology and confirmed previous results, the latest of the studies were the most extensive. This study conducted a comparison of earnings for veterans and non-veterans for World War II, Korea, and Vietnam. The results indicate that minority veterans for all three wars had accrued premiums that could be attributed to military service. However, white veterans of the Vietnam period experienced an earnings penalty.

Martindale and Poston only controlled for education, employment and marital status as income earning factors.

24

Their studies failed to control for tenure, and training, two variables that have considerable impact on income. However, their study did highlight other important variables, such as the influence of the socio-political climate. Therefore it is suggested that veterans of the different wars not only faced different selection procedures, but also had to contend with different social and economic conditions on their return.

Thus it is important when examining the results on any study on post service benefits to analyze both the "representativeness" of the veteran sample and the prevailing economic conditions. Most studies fail to clearly indicate or control for veterans superiority or inferiority in many factors that contribute to earnings. Table 1 gives a concise summary of the three University of Texas studies.

4. Little and Fredland (1980)

Little and Fredland (1980) hypothesized that military service itself serves as a general training variable adding to one's investment in human capital and therefore contributes to post service earnings. Their results were obtained from the 1966 NLS survey of men aged between 45 and 59 in 1966 and indicate that regardless of race, veterans had significantly higher average earnings than non-veterans. Using regression analysis, they conclude that schooling completed and job tenure had positive effects on income, but age had a negative effect. This appears to be inconsistent in that OJT and

firm specific training gained with age would improve productivity. The models used by Fredland and Little were the traditional linear and semi-log formulations:

$$\text{Linear:} \quad Y = b_1 + b_2 X_2 \ldots b_n X_n$$

$$\text{Semi-log:} \quad Y = e^{b_1 X_1 \ldots b_n X_n}$$

The models utilized both wages and salaries, and annual income as dependent variables. A summary of the independent variables employed are given in Table 2.

A possible explanation of the positive results accruing to veterans is the composition of the sample. World War II veterans served in a period of no college exemptions and little draft avoidance. This resulted in a good cross section of the population serving in the military [Fligstein, 1980] and [Moskos, 1970]. In addition, veterans returned home as popular heros to valuable G.I. Bill benefits. That era also saw a period on industrial expansion and economic growth which provided good employment opportunities. Moreover, since Little and Fredland used a cross-sectional analysis that looked at veterans and non-veterans incomes reported for one year (1966), twenty years after the war, lifetime benefits to veterans could not be established. It would be incorrect however to infer a veteran premium for each year since a service member's return to the civilian sector.

5. DeTray (1980)

DeTray's (1980) study led him to the conclusions that:

a.   Veterans earn more than non-veterans.

b.   Training received in the military increases
civilian wages when innate differences are controlled.

The model hypothesized by DeTray was;

$$Ln(W) = a_0 + a_1 E + a_2 X + \sum a_i \, OF_i$$

where $Ln(W)$ is the natural log of an individual's wage rate
per hour, E is the level of education, X is years of job
experience, and OF is the level of other factors. Job
experience was broken into two factors; years of actual job
experience and tenure with current employer. As shown in table
2 the other independent variables were typical of previous
studies in this area.

The data set used by DeTray was the 1971 NLS of
young men, 14-24 years old in 1966. He found premiums attri-
butable to veterans status of approximately 10 percent. Due
to the low number of black veterans (40), DeTray considered
that little value could be placed on the negative 6 percent
return to black veterans determined by his equations. One
weakness of DeTray's study was the assignment of veteran status
to anyone who indicated they had been in the military. This
definition possibly included those who did not really experi-
ence the disruption of extended military service.

Although DeTray's work was extensive, he states
that his report only hints at the direction of the likely
outcome of a more complete analysis of military training.

Final and conclusive results he felt would have to wait until the full ten years of the NLS survey of young men was available.

6. Bolin, Hess and Little (1980)

The Bolin, Hess and Little (1980) study was conducted using the NLS of young men, 14-24 years old in 1966, with 1969 and 1971 data. In particular, this study addressed the effects of vocational training received in the military on post service earnings. They concluded there were no positive economic benefits to be gained through military training in the short run. Variables used in this study were similar to those of the previous studies except for the inclusion of a training variable. This variable indicated whether the member used vocational training on the job. Three different dependent variables were used: hourly pay rate, the log of hourly pay rate, and annual wages. The other independent variables were typical of previous studies and included age, education and tenure. In particular, their results indicate that veterans who did not receive vocational training in the military would have done better using their time to gain tenure in a civilian job. Like DeTray, Bolin, et al., indicate their study is limited to the short run and must await further releases of the NLS of young men to verify their study. What is of interest, however, is that both these studies, DeTray, and Bolin et al., employed the same data but had differing conclusions as to returns accruing to veterans. These studies highlight the importance of methodology and its ability to influence results.

F. SUMMARY OF STUDIES

Table 1 contains a short summary of the studies reviewed.
Briefly stated are the purpose, data base, methodology and
findings. In addition Table 2 details those factors or
attributes that were considered in these studies.

This review reveals why results as to the benefits of
military training and work experience in post-service earn-
ings vary in their conclusions. In particular, it can be
seen that most of the studies used different explanatory
variables. Griliches (1977) reports that normal analysis
procedures which delete discriminating variables can invali-
date or confound research results. By reviewing Table 2, it
is possible to hypothesize some studies may not have controlled
for variables which may have influenced conclusions. This
aspect is highlighted by DeTray (1980) and Bolin et al.,
(1980), studies which used the same data base but had con-
flicting results.

Cutright (1972) and Martindale et al., (1979), indicate
that a selection bias in the veteran sample arises from the
political and socio-economic climate of the time of enlist-
ment. Thus the quality of persons entering the military may
vary from period to period. Further, the political and economic
climate at the time of discharge may also greatly influence
post service opportunities. The Martindale et al., (1979)
study is one of the few studies that replicates the same
methodology on different cohorts to highlight the effects of
a changing environment.

29

Possibly the greatest shortcoming of all studies reviewed are their failure to demonstrate lifetime benefits attributable to veteran or non-veteran status. At best, their use of limited longitudinal analysis can only hint or infer the likely direction of these results. The analysis of lifetime earning benefits would only be possible by conducting a longitudinal survey, from which earning profiles of individuals could be traced. Despite some of the shortcomings of the studies reviewed, each has made a valuable contribution to extend the body of knowledge as to the effects of military service on post service earnings. In addition, these studies helped formulate the basis of the methodology used in this thesis.

TABLE 1

A SUMMARY OF STUDIES REVIEWED

AUTHORS AND DATE	TITLE AND PURPOSE	DATA BASE	METHODOLOGY	RESULTS AND CONCLUSION
1. Cutright, P. 1972	Achievement, mobility & the draft: Their impact on earnings of men. Analyzed the determinants of earnings & changes in earnings to measure the effects of military service on post service earnings.	Selective Service Files, 1% sample in 1953. Linked with Social Security Data in 1958 and 1964.	Used a comparison of Army veterans & non-veterans. With controls for age, education, race and IQ (AFQT) at two time points, 1958 and 1964.	The earnings of veterans are not higher earnings for comparable non-veterans. Programs that remove men from the labor market depress post program earnings.
2. Nordblom. E. 1976	The Returns to Military & Civilian Training. Study examines the economic effects of formal military training & on-the-job training acquired while in the military.	Post Service Information File for FY71. 25% of all Army, Navy, and Air Force separatees who left military service after one term.	Regression analysis semi log function. Blacks excluded from the analysis. No comparison of veteran/non-veteran was conducted.	Formal vocational training tends to have a positive significant effect on post service wages.
3. Browning, H. Lopreato, S. and Poston, D. 1973	Income & veteran Status Variations Among Mexican Americans, Blacks and Anglos. Study the effect of military service on minority men with emphasis on the "bridging environment"	1960 Public Use Sample. 1% of all men over 14 years classified as veterans in the five southwestern states.	Used a comparison of mean income controlling for race, education and occupation.	Income advantages displayed by minority group veterans over non-veterans support the bridging environment hypothesis.

TABLE 1 (CONT.)

AUTHORS AND DATE	TITLE AND PURPOSE	DATA BASE	METHODOLOGY	RESULTS AND CONCLUSION
4. Lopreato, S. Poston, D. 1977	Differences in Earnings and Earnings Ability Between Black Veterans and Non-Veterans in the United States. Study tests effects of "bridging hypothesis" of military service.	1% sample of 1970 U.S. Census of Population aged 25 & 54.	Comparing annual earnings after running two separate regression analyses by veteran status, controlling for education. Other controls for age and employment were imposed by sample selection.	Black veterans are better able than black non-veterans to convert educational attainment into earnings advantage.
5. Martindale, M. Poston, D. 1979	Variation in Veteran/Non-Veteran Earning Patterns Among World War II, Korea and Vietnam War Cohorts. Study tests effects of civilian attainment by color and varying political & economic influences.	1% sample of 1970 U.S. Census Population Sample restricted by age & period. WW II (1940-1947) Korea (1950-1955) Vietnam (1964-1970).	Comparison of annual earning after running two separate regression analyses by veteran status, controlling for education, employment, marital status & of course, race.	Black and Mexican American Veterans are better able to convert characteristics into earnings than their non-veteran counterparts. For whites the Vietnam period gave non-veterans an income advantage.
6. Little, R. Fredland, J. 1979	Veteran Status, Earnings, & Race: Some long term results. Study examines earnings of veterans/non-veterans some 20 years after most served.	NLS of men aged 45-59 in 1966.	Regression analysis controlling for many factors that contribute to earnings. Study was cross sectional.	Veterans had a 5% to 10% premium on earnings.

32

TABLE 1 (CONT.)

AUTHORS AND DATE	TITLE AND PURPOSE	DATA BASE	METHODOLOGY	RESULTS AND CONCLUSION
7. DeTray 1980	Veteran Status and Civilian Earnings. A detailed examination into causes of differences in civilian earnings between veterans and men with no military service.	NLS of Young Men aged 14-24 in 1966. 1971 data set used.	Regression analysis controlling for many factors that contribute to earnings. Study was cross sectional.	Veterans earn more than non-veterans. Training received in the military increases civilian wages
8. Bolin, P. Hess, M. Little, R. 1980	Military Vocational Training: Its Impact on Post Service Earning Path. This study utilizes human capital approach to compare the values of civilian vocational training over time.	NLS of Young Men aged 14-24 in 1966, 1969 and 1971 data is used.	Regression analysis controlling for many factors that contribute to earnings, in particular the use of civilian and military training.	Use of military training does not have a positive effect. Those veterans who receive no training but have military service have a negative influence on their earnings.

III. METHODOLOGY, DATA BASE AND SAMPLE SELECTION

A. INTRODUCTION

To ascertain whether military service enhances future earnings, and can therefore be considered a viable alternative method of investing in human capital, it is necessary to test the following hypotheses.

1. Personnel who enter and complete a tour of military duty are a representative sample of their cohort or population group.

2. The earnings effect of military service is no different from obtaining work experience and training in the civilian sector.

3. The type of military participation undertaken with regard to branch of service, length of service, length of training or time of service has no effect on future earnings capacity.

In this chapter it is intended to outline the methodology employed to test the above hypotheses, give details of the data base used in the study, and present the criteria applied in the selection of the sample for the analysis.

B. REPRESENTATIVENESS OF VETERAN COHORT

The first hypothesis was tested by examining a number of factors that are considered relevant by current literature as influencing the generation of income and life-cycle benefits. Each factor was examined in turn to establish if the distribution of the factor was similar in both the veteran and non-veteran sample. If all factors proved not to be statistically different, any observed difference in income could therefore

35

be assumed in part to be attributable to the influence of military training and experience. If some factors were distributed differently among veterans and non-veterans, then those factors would have to be included in a multivariate explanation of earning differences.

The factors chosen have been grouped under four categories: individual traits, family circumstances, personal characteristics, and job environment. The list of factors is not exhaustive, and categories are not mandatory. However, the factors include those most frequently used in the construction of a human capital earnings equation as found in the current literature. Categorical groupings for each factor involved arbitrary judgment, and were selected so as to facilitate discussion purposes.

1. Individual Traits

These are defined as factors which influence income capacity, but are generally beyond the individual's discretion to alter. The factors chosen are health, age, and intelligence. All three factors directly and indirectly affect earnings. Age is not only related to work experience and ability, but also poses limitations on the achievement of particular goals. For example, obtaining a car license, financial independence or even a particular level of schooling is not possible until the individual has reached a certain age. Similarly, health can restrict the scope and capacity of an individual to undertake a particular occupation. Many

36

jobs today also apply minimum psychological and physiological entry standards for selection, which may restrict the job opportunities for an individual. Moreover, failing health may also directly affect the number of hours, and weeks worked by an individual and therefore may have a considerable impact on annual and weekly earnings.

Native intelligence, like age, and health, has both a direct and an indirect influence on earnings. Intelligence has been found to be strongly related to school achievement. This in turn enables the more intelligent, and educated person greater access and opportunities to higher paid employment. In addition, intelligence is related to "trainability," which reduces training costs to employers and tends to make the member a more productive person faster.

2. Family Circumstance

Two factors have been placed under this heading. The first relates to the socio-economic home environment of the individual in his formative years. The greater the level of family wealth and education experienced by an individual, the more conducive is the atmosphere for his educational and social development. Home environment no doubt also greatly influences attitudes, and motivation to work. Positive home influences, and encouragement contribute considerably to the aspiration, and achievement levels of individuals seeking later financial rewards.

In a similar manner, marriage influences or modifies individual behavior in a positive manner. Employers attribute

37

a greater sense of responsibility and steadiness to married employees and to those with dependents. Job application forms and job interviews tend to confirm that employers are more willing to employ married personnel. A review of employee turnover studies by Mobley (1979) confirmed that marital status and having dependents was associated positively with tenure, while the highest turnover ratio was by employees who were single. Marriage, and dependents thus may reduce mobility and irrational "quitting" behavior. Hence, returns to employers on training is more profitable and secure.

3. Personal Characteristics

Two factors, education levels, and vocational training, are placed in this category. As seen in the literature review, both of these aspects are established as having an important relationship to income generation. Education is greatly influenced by individual intelligence and family wealth. While education may signal to employers a general capacity of an individual for training, it may also be used to indicate positive work attitudes like perseverance, diligence, and motivation. These attributes have the general effect of improving employee productivity and also enhancing the individual's employability in all jobs. Vocational training on the other hand is normally considered to be job-specific; that is, to improve individual skills and productivity in a particular occupation. In many instances, however, vocational training may also be used as a stepping stone to higher paid positions in the instructional, managerial, and supervisory

fields. These positions would have been unattainable, except for the prior vocational training undertaken.

4. Job Environment

This category includes many factors related to location and time. Two aspects of location were considered pertinent. The first is related to labor market size. Here it was assumed the size of the individual's local labor market would be influential in the range of available occupations, as well as increasing the opportunities for a competitive labor market. In addition, participation in a large labor market would assist the individual's job mobility without necessarily involving family and home movement.

Regionally, it has been found that lower wages are paid in the southern states. A variable was therefore included to account for this geographical wage differential.

It was also necessary to include job specific factors that accounted for length of service with current employer, weeks of employment, and hours worked. Length of service or tenure not only increases experience, and job expertise, but also is often rewarded by employers with increasing annual salary increments for improved productivity, and loyalty. In addition, length of service adds advantages like larger bonus payments, first choice at overtime, and in union controlled industries "first on, last off" privileges.

Aspects like number of weeks worked per year or average hours worked per week have an obvious direct relation to annual income. It was therefore necessary to account for

these variable influences when comparing the veteran and non-veteran groups. Two measures of income were also utilized, hourly rate of pay and total income from wages and salaries.

Chapter IV deals in detail with each of the above factors. It gives a precise definition for the construction of the variable and then presents the descriptive statistical data and tests for each factor.

C. EARNINGS EFFECT OF MILITARY EXPERIENCE

In Chapter V, the study uses the variables developed and defined in Chapter IV to examine the simultaneous effects of these factors in the determination of income. In particular, the multiple regression analysis presented in Chapter V is based on the logarithmic formulation of the human capital model of wage determination as developed by Mincer (1974).

There are two human capital earnings models developed in this study. Each proposes that an employees wage is determined in part by the amount employers are willing to pay for personal factors that contribute to productivity. Thus, the quality and quantity of income earning factors, naturally possessed or developed by workers, are in part responsible for their received wage and salary. These models are best formalized by the equation:

$$Ln(W) = a_o + a_1 v + \sum_i a_i (EF)_i$$

where Ln(W) is the dependent variable. In model 1, W is an individual's hourly wage rate, and in model 2 W is the

individual's annual income. In the models, v is the dummy variable indicating veteran status, and the (EF)'s are all the other earning factors that influence wages and salaries. An appeal of the logarithmic formulation is that the coefficients (the a_i's), can be interpreted as percentage changes in wages received as a result of one unit change in the independent or explanatory variables. It is also possible to interpret these coefficients as the rates of return to acquiring an additional unit of the independent or explanatory variable.

It is intended to use only "pure" data in the forward stepwise regression analysis. That is, any case that does not have all factors present will be deleted from the analysis. In addition, the derived equation will be examined to determine if the overall F value for the equation is significant, and to determine the "goodness' of fit of the equation by examining the value of the R^2.

One of the deficiencies of a cross-sectional analysis of this type is that only 1976 earnings have been examined. To determine if there are life-cycle benefits to be gained through military service, it would be necessary to undertake a longitudinal study and plot received wage rates over time. A longitudinal study would be more meaningful as it would establist a time path for individuals enabling us to assess the effect of time on military service. That is, it would be possible to see if wage differentials between veterans and

non-veterans increased or diminished over time. In an attempt to simulate time paths of earnings it is intended to disaggregate the veteran and non-veteran sample by age. This analysis would, of course, assume that all age groups are similarly affected by all other attributes. If this assumption holds, it would then be able to proxy age for time and develop a longitudinal wage curve showing the increasing or decreasing effects of veteran status over age (time).

D. SERVICE SPECIFIC EFFECTS

The final hypothesis tested whether the type of service participation by veterans was a contributing factor on post service earnings. In addition to the factors discussed earlier, variables were constructed to cover the following service aspects.

1. Branch of Service the Respondent Entered

This indicates whether the respondent served in the Navy, Army, Air Force or Maine Corps. This factor had to be considered because, on the average, the Navy and the Air Force require people of a higher level of technical skill than do the Army and the Marine Corps. Thus, the training given in these services tends to be longer and have more compatibility with civilian requirements.

2. Months of Completed Additional Military Training

Training above basic or boot camp training was considered an important factor. Not only is the member more likely to use this training as a basis for later civilian

employment, but it also indicates that he was screened by service criteria as eligible for further training.

3. Period of Time Spent in the Military

This was included as a factor because it can have two effects. Those who remain for longer periods are normally chosen to undergo further training, and may gain additional work experience and education. However, time spent in the military also detracts from time the member may be using to increase tenure and receive specific training.

4. Aging Effect of Military Service

A variable was introduced that measured the time since the member left the military service. Obviously the more distant the period of prior service, the greater the opportunity the individual has had to search for an appropriate job, use G.I. Bill benefits to undertake further education or vocational training or build up his tenure with his employer.

A statistical description of these factors is given in Chapter VI. In addition, multiple regression analysis was used to determine the significance of these factors in the generation of income.

E. DATA BASE

The data used in this analysis are from the 1976 National Longitudinal Survey (NLS) of young men who were aged 14 to 24 years in April 1966. This survey is one of many conducted by the Center of Human Resource Research of the Ohio State

University. The Center was contracted by the Office of Man-
power Policy, Evaluation and Research of the United States
Department of Labor to survey four age groups: Men 45 to
59, Women 30 to 44, Young Men 14 to 24 and Young Women 14 to
24 years of age. These age groups were selected to reflect
the specific and different labor market problems faced by
each group. For the young men, the survey was designed to
obtain extensive information as to the process of schooling
and vocational choice. Moreover, the NLS data represent
the best available longitudinal data from which a sample of
veterans and non-veterans could be drawn.

The young men's survey intended to examine closely the
preparation for careers, as well as the problems encountered
in adjusting to the labor market during the difficult transi-
tion period from school to employment. In addition to the
respondents' labor market behavior and experience, a substan-
tial quantity of data were collected on the respondents'
personal characteristics and family circumstances. To date
there are over 5,000 pieces of information on most members of
the original sample.

The original NLS sample did not include anyone who was
serving in the military in 1966. Fortunately, this group of
14 to 24 year olds contains the primary age group from which
the military services draw recruits. Thus, actual numbers who
experienced military service were sufficient for statistical
analysis. The survey was initially intended to cover a period

of five years from 1966 to 1971, but was later extended by an additional five years due to the low attrition rate among respondents.

An original sample of 5,225 non-institutional young men 14 to 24 years of age was randomly selected by the Bureau of Census from sampling units that had been selected to conduct the experimental Monthly Labor Survey during 1964 and 1966. However, to ensure sufficient minorities were included, the sample was biased to over-represent minorities in the sample by a three to one ratio to their proportion in this population. To ensure results are not biased, most of the analysis presented in this study is produced separately by race.

F. SAMPLE SELECTION

Final selection of the subsets employed in the analysis was based on the following criteria.

Set 1, Veterans: This set contained survey members who were classified as veterans. Veteran status was only assigned to those members who had completed 24 months or more in the military by 1976. Veterans in this category averaged 37 months of service.

Set 2, Employed: For survey members to qualify for inclusion in this set, they were required to be fully employed in 1976. Classification of full employment had been arbitrarily set to include only those members who were working 35 hours per week or more.

45

Set 3, Short Term Enlistees: Those who enlisted, but did less than 24 months of service in the military were as-signed set 3 status. This set of members were excluded from any further analysis, as it tended to include those who attrite from the service or those who are reservists. Thus, the final sample selected for analysis was the intersection of sets 1 and 2. This in fact meant that the sample included all those individuals who were working 35 hours or more per week and had never joined the military, or if they had enlisted had completed 24 months or more of military service.

The effect of applying these criteria is highlighted by examining Figures 2, 3 and 4. Figure 2 shows an original data base of 3627 respondents in 1976; 2395 non-veterans and 1232 individuals with some military service. The application of the two year veterans criterion reduced the usable sample to 3114 (as shown in Figure 3), of whom 2395 were non-veterans and 719 were veterans. The final sample used in all the following analyses was derived by the joint application of veteran status and full employment criteria and is shown in Figure 4. Here the total usable sample size is reduced to 2431, and is comprised of 1868 non-veterans (466 black and 1402 white), and 563 veterans (121 black and 442 white).

An examination of the average income earned by each group as the different criteria are applied is interesting in that the "some military" service group had a higher average income than the 2 year veteran group ($10,223 to $9,968). However,

46

when the full employment criterion was applied, the average wage for veterans rose to $11,339. There are two possible explanations. Firstly, the employment criterion removes those veterans who are still undertaking further vocational or educational training, but had part time jobs. The second explanation is that the percentage of black veterans in Figure 3, who on the average earn less than the whites, is higher than the percentage of black veterans in Figures 2 or 4. Situations of this type highlight the appropriateness of conducting this study for the black and white samples separately.

For the non-veteran sample, using the full employment criterion raised the average earning in excess of $1,700, but reduced the sample size by 527. These figures would indicate that there are many parttime workers in society. Surprisingly enough, the percentage of part employed workers was identical for both groups, and was 22% of the sample size.

A limitation of the selected sample is that there is a potential bias. There are possibly members who are still enlisted in the military who may have gained the most through military service. As the NLS does not interview respondents during their military tour, it is impossible to determine this number. In addition there was no method of determining whether the youths who undertook military service avoided periods of unemployment and were thus economically better off during their period of enlistment. However, as the main aim of the study is to assess the contribution of military service to

the future earnings of a non-careerist, this limitation does not detract from the study.

G. SUMMARY

This chapter has outlined three aspects of this study.

1. The three hypotheses to be tested, in relation to veterans and their post service earning capacity.

2. The approach and methodology to be followed in the examination of the hypotheses.

3. The selection criteria applied in drawing the veteran and non-veteran sample in this study.

Chaters IV, V and VI which follow, give greater details of the definitions of variables employed, the statistical techniques used and the results obtained from the analysis.

IV. REPRESENTATIVENESS

A. INTRODUCTION

This chapter examines the similarities and differences
between the veterans and non-veterans in the sample. Each
of the factors discussed in Chapter III is analyzed as a
continuous or as a categorical variable. Most of the statis-
tical techniques used to describe and test each variable are
from the Statistical Package for Social Sciences (SPSS).
Specifically three test statistics were employed.

1. Difference of Means Test

All continuous or assumed continuous variables were
tested by the SPSS Oneway ANOVA procedure to determine if
the difference between the mean values of each variable for
veterans and non-veterans was significant. These results are
found at the top of each table. Each table is standardized
in a format that gives the variables name, the mean, standard
deviation, and sample size of the veteran or non-veteran
group that was used to calculate those statistics. Next,
follow the degrees of freedom (D.F.), the "F" test value,
and the probability (P), that the difference could occur by
chance.

2. Chi-Square Test

This utilizes a joint frequency distribution of cases,
which summarizes the relationship in matrix form. Given are
the actual numbers and percentages of the group sample

population found in each cell. The tabulation is statistically analyzed by the Chi-Square test of independence to determine whether a systematic relationship exists between the two variables. However, Wonnacott (1977) warns that, "when a sample is large even minuscule deviations will generate statistically significant χ^2." Therefore, the reader is warned to treat the resulting χ^2 with caution. More important, however, is that the table presents the distribution of the variables in a meaningful manner which can assist insight far greater than a mean and standard deviation.

3. Kolmogorov-Smirnov Test

Where variables were grouped to facilitate the use of the SPSS Crosstabs Program, the Kolmogorov-Smirnov two sample test was also conducted. This test determines whether two independent samples have been drawn from the same population or populations with the same distribution. In particular, the two tail test is sensitive to any kind of difference in location of means, skewness or kurtosis. Basically the test is concerned with whether there is agreement between the two cumulative distributions. The greatest difference between the two cumulative distributions is identified and tested against the greatest acceptable difference. That is, if the two samples cumulative distributions are identified as being too far apart at any category, the test results lead the researcher to infer that the samples come from different populations.

The strength of the Kolmogorov-Smirnov test is that it seems to be more powerful than the Chi-Square test [Siegel, 1956]. In addition, it is most suitable where categories have been arbitrarily set, as was done in this study. Moreover, whereas numerous categories weaken the Chi-Square test, the greater the number of categories in a Komogorov-Smirnov test, the more accurate the result.

B. CRITERION VARIABLE

1. Veteran Status

Veteran status was a dummy variable assigned a value of one for those members who had served twenty-four months or more in the military. Those who had never served in the military were assigned the value of zero. Most previous studies, due to data limitations (small number of veterans), were forced not to apply any minimum length of service requirement. The two year minimum service requirement in this study is considered an appropriate measure of military service for the following reasons:

a. Veterans have a greater period of time to receive additional or advanced training.

b. There is a longer indoctrination period for veterans to absorb those desirable work values often attributed to military work experience, and general training.

c. It removes members of the Enlisted Reserves (ER's) from the sample. These members did only six months full time service and would not have suffered the disruption of typical military service on employment, or received advanced training.

d. It removes from the "veteran sample" those personnel who are actually unsatisfactory for military service. Thomas (1977) found that in the Navy most early attrition

54

or discharges, within the first two years, are due to
psychological and physiological deficiencies, fraudu-
ent enlistment or criminal activities. In particular,
seventy three percent of those who were discharged
within the first two years left with dishonorable dis-
charges. This would indicate substantial nonproductive
behavior, among attriters. It is assumed other ser-
vices would have similar figures. In addition, it is
assumed that the removed service members are not
"typical" of the better and more commonly found mili-
tary service personnel working in later civilian
employment.

e. There is a better assessment as to the possible effects
of the draft. Traditionally, the two year draft period
has been considered one that is economically viable to
the services with regard to returns on training. A
two year enlistment is also seen as minimizing the
disruption to the lives of the individuals who are
drafted.

C. EARNING FACTORS FOR VETERANS VERSUS NON-VETERANS

1. Hourly Rate of Pay

HRLYPAY: This continuous variable measured the
respondent's hourly rate of pay at his current or last job
in 1976.

HOURPAY: Is a categorical derivation of the hourly
rate of pay. HOURPAY was constructed by grouping hourly pay
into a number of categories. This grouping permitted the
SPSS crosstabs program to be used. Table 3 gives the pertinent
descriptive statistics for these variables when disaggregated
by race and veteran status.

Each table in this chapter is presented with the re-
sults for blacks, followed by the results for whites. The
results for each race give the mean, the standard deviation,
and the sample size for the black non-veterans and veterans.

55

	8.1	7.1	7.9
$9.00 to $9.99	58	14	72
	4.3	3.2	4.0
GE $10.00	111	26	137
	8.1	6.0	7.6
Column Total	1362	436	1798
	75.8	24.2	100.0

$\chi^2(8) = 14.31$ significance = .07*

Kolmogorov-Smirnov Test: D = 4.3% = .043
                          significant at .01 level if D $\geq$ .089
                          significant at .05 level if D $\geq$ .075

Thus, from Table 3, for hourly pay rate, black non-veterans had a mean hourly wage of $4.40 and a standard deviation of $1.87. [Both calculations were derived from a sample size of 448.] Black veterans, on the other hand, had a mean hourly pay rate of $4.77 with a standard deviation of $1.82 from a sample size of 119. The degrees of freedom (D.F.) of 1 and 565, for the test of difference of means between black veterans and non-veterans, are also given in Table 3. The "F" test value was 3.67 which resulted in a type I error probability value (P) of .06. At this probability value, we would accept at the .05 level of significance the null hypothesis that there is no difference in hourly rate of pay between black veterans and black non-veterans.

The crosstabulation format is presented so that the reader can gain an appreciation as to the distribution of the variable for veterans and non-veterans. The top figure in each cell is the actual number that belongs to that category, while the lower number in each cell give the column percent for that cell. For blacks, the first non-veteran cell shows 106 members who represent 23.6 percent of the column sample size of 448. At the bottom of the crosstabs table is the Chi-Square statistic of 10.44. At five degrees of freedom, this resulted in a .06 significance level. Following the Chi-Square test are the results of the Kolmogorov-Smirnov test. The value of the Kolmogorov-Smirnov test at both .01 level (.168) and .05 level (.140) are shown. Also given is the

absolute maximum difference, "D" (.124) that occurred between any two categories. To be significant at the .01 level, "D" would have had to be equal to or greater than .168.

After the blacks, the data for the whites follow the same format. Shown is the difference of means test, the crosstabs table with the Chi-Squared statistic, and finally, the result of the Kolmogorov-Smirnov test. This format is standardized for all continuous variables in this chapter.

All statistical tests for whites on the data proved to be insignificant. This would indicate that the comparative hourly earnings between white veterans and non-veterans are very similar, and no cohort displayed any advantage.

2. Annual Income

Y(income): This continuous variable measured sampled members total income received from wages, salaries, commissions, tips and gratitudes, and bonuses during 1976. Census regulation confidentially rules, however, do not allow amounts in excess of $50,000 to be shown. Thus, all values in excess of $50,000 are reported as $50,000. This modification should not substantially influence results because of the small numbers exceeding the $50,000 limit.

INCOME: A categorical grouping of annual income (Y) was necessary to enable crosstabulation depiction. Here annual income earned from wages and salaries was formulated into arbitrary categories. Relevant statistics of these two variables are shown in Table 4.

Kolmogorov-Smirnov Test: D = 6.9% = .069
significant at .01 level if D $\geq$ .089
significant at .05 level if D $\geq$ .074

It can be seen from Table 4 that there was no significant difference for blacks between the average incomes earned by veteran and non-veterans. When grouped into table form, the Chi-Square test showed a significant relationship existed between variables at the .1 level. However the Kolmogorov-Smirnov test, showed no significant difference between the two distributions existed. The significant Chi-Square is obviously due to the large numbers of cells created when the variable was categorized.

For whites, however, all tests except the Kolmogorov-Smirnov test were significant at the .05 level. This result indicates that in respect to average income, white non-veterans, on the average, have higher incomes.

Both hourly rate of pay and total income from wages and salaries are considered by be "key" variables by the NLS Center. Because of their importance and wide use in research studies, these variables have been specifically constructed, assessed, and unrealistic values edited by the NLS Center.

3. Marriage, Health, SMSA, Region and Vocational Training

A number of dichotomous or dummy variables were used during the analysis. All dummy variables were tested only by the Chi-Square statistic. However, all the cells met the requirement to have a greater expected frequency count than 5. Each table is standardized in the same format for each dichotomous variable.

a. Marry

If the respondent indicated he had never married, he was assigned the value zero. All other cases were given

the value one. An examination of Table 5 for blacks, indicates

that in cell 1, there were 102 black non-veterans who had

never married. This figure is 21.7 percent of all black non-

veterans, while in cell 2, the 369 married black non-veterans

comprises 78.3 percent of the black non-veteran sample. Row

percentages show that of the total sample of black veterans

and non-veterans 21.6 had never married while 78.4 were

married. The low Chi-Square statistic of .006 at 1 degree of

freedom infers that there is no difference in the marriage

pattern of black veterans and non-veterans. For whites, how-

ever, the Chi-Square value of 4.87 indicates that white vet-

erans are more likely to be married than white non-veterans.

The greater propensity of white veterans to be married is

possibly in part due to the fact that the average age of white

veterans is also significantly higher, than for white non-

veterans. This places them in a more marriage eligible group.

Black veterans, however, are younger than black non-veterans,

but not significantly. Therefore, black veterans and black

non-veterans possibly have a similar marriage pattern.

  b. Healthy

  When respondents indicated that their health did not

prevent nor limit their work activities, they were allocated

the value one. Positive answers by respondents were assigned

the value zero. Table 6, which details the results of the

statistical tests on the health status of veterans and non-

veterans, shows that there is no significant difference between

65

black veterans and non-veterans. However, white veterans show that they are significantly more healthy, or health limits their work capacity for less than their non-veteran counterparts. One would expect veterans to be healthier since they must pass basic medical and physical tests and are encouraged to partake in physical activities. In addition, service physical and medical tests should not be underestimated. In a recent survey, Borack (1980) found 37 percent of the male population, aged 17 to 24 would not qualify for military service based on medical or physical standards. These figures would indicate that veterans in general should lose less time through illness and possibly be more suited to work in demanding environments.

c. SMSA

There are 288 standard metropolitan statistical areas (SMSA) in the United States of America. In particular, a SMSA consists of either a central city having a population in excess of 50,000 or may be adjacent counties affiliated with a central city economically and socially. Respondents residing in a SMSA in 1976 were allocated the value one with non-SMSA residents given the value zero. Table 7 gives the results of the analysis as to the residential status of veterans and non-veterans. It can be seen from this table that both black and white veterans have statistically significant propensity to reside in SMSA's. If SMSA's offer a greater variety of occupations and are more competitive for labor,

TABLE 7

$\chi^2(1) = 2.99$ significance $= .08$*

67

then veterans are in a position to earn more than their non-veteran counterparts. It would appear from these results that veterans are either more aware of the greater job opportunities offered by SMSA's, or are drawn to occupations that are situated in SMSA's. Either reason should provide a more favorable wage differential for veterans.

d. REGION

If a respondent was residing in the South in 1976, he was assigned the value one. Other areas of the United States were allocated the value zero. An examination of Table 8 indicates no statistical difference in the residential patterns of veterans and non-veterans with respect to these geographical regions.

e. VOCTRG

This variable related to questions asked of respondents as to whether they had ever undertaken any formal occupational training or educational courses that did not lead towards an academic diploma or degree. It is assumed that members who had undertaken such training were intent on enhancing their job skills, and productivity for improved future earnings. Table 9 indicates that both black and white veterans undertake statistically significantly more vocational training than their non-veteran counterparts. No effort has been made to assess the length of this vocational training. In fact the variable only identifies those members who were either motivated, had the opportunity to do training, or were

considered "trainable" by their employers. Any respondent
who gave a positive answer, at any time, was given the value
of one, while all other cases assumed the value of zero.

4. Age in 1976

AGE76: This variable reports the respondent's age
in 1976. The range extended from 24 to 34 years of age.
Table 10 provides the crosstabulation and descriptive data
when age was disaggregated by race and veteran status. The
age table for blacks shows that there is no difference in the
overall means for black veterans and non-veterans. However,
the Kolmogorov-Smirnov test does indicate that the distribu-
tion between black veterans and non-veterans is dissimilar.
The reason for this variance in results is due to the very
low percentage of black veterans in the group of 27 year olds.
There would seem no apparent reason why this lower number
should occur, other than by chance.

For whites, veterans are statistically significantly
older than non-veterans. A possible reason for this differ-
ence is offered by the Kolmogorov-Smirnov test which proved
significant at the .05 level. The difference "D" indicates
a high cumulative percentage of whites at the 28 year old
level in the veteran group. A historical perspective, would
indicate that the 28 year olds were of prime "draft eligible"
age during the Vietnam build-up. It is not surprising there-
fore that a large percentage of that age cohort are veterans.

5. Education

HGHSTED: The respondent's highest attained grade of education is given by the variable HGHSTED. Because education is a key determinant of future income and earning power, two categorical derivations of education were also constructed.

1. SCHOOL: This variable has six groups and highlights those who attained high school diplomas and college degrees.

2. EDUC: This variable is categorized into three levels; elementary, high school, and college attendance.

For blacks, it was found that veterans were statistically significantly better educated than non-veterans. An examination of the categorical variable SCHOOL indicates that the lower levels of education statistically vary from the higher levels when tested by the Kolmogorov-Smirnov technique. This is not surprising, as it confirms service recruitment policy. From Table 11 it can be seen that the military has recruited very few elementary or only high school educated blacks. The majority of the blacks recruited are high school graduates or those with some college. The reason for this recruitment policy is because education level is used as a prime criterion indicating whether recruits will complete their enlistment period. Lockman (1976) showed that non-high school graduates have the highest propensity to attrite, regardless of mental group category.

For whites, it was found that non-veterans had a statistically significantly higher level of education. In addition, a close examination of the categorized educational

variables again confirms military service recruitment policy. Most of the military recruits belong to the high school graduate and some college groups. The high percentage of non-veterans that complete college or higher, is sufficient to compensate for the poorly educated non-veterans and results in the non-veterans education level being statistically significantly higher than white veterans. These results are found in Table 11.

6. Tenure

TENURE: This is the variable used to describe the actual number of years the respondent had been working for his current employer. However, the member may not necessarily be in the same job in which he started, due to promotion or training.

JOBYEAR: As the range of tenure extended from one to twenty-three years for blacks, and from one to nineteen years for whites, it was considered convenient to group the few who had more than eleven years tenure. This produced a categorical variable JOBYEAR. Statistics related to these variables are given in Table 1? It can be seen from Table 12 that for both blacks, an. ... , non-veterans have statistically significantly higher mean tenure than veterans. The Kilmogorov-Smirnov test also infers that the two groups differend in their distributions. It would appear that veterans have a far greater positive skewness to their distribution than non-veterans. The obvious reason for this positive skewness is that military service has detracted from veterans

the opportunity to gain years of service with the same employer. It can be seen from the table that for black veterans 32.8 percent have one year tenure, but only 5 percent have 11 or more years tenure. Black non-veterans, however, have only 18.7 percent with one year tenure, but approximately 10 percent of their group has 11 years or more of tenure. Similarly, white veterans are also effected having smaller group percentages with high tenure and a large group percentage with a low tenure than do the non-veterans. For example, 23 percent of white veterans have one year or less tenure compared to only 18 percent of the white non-veteran group with one year or less tenure.

7. Weeks of Employment

WKSEMP: The WKSEMP variable counts the number of weeks of full employment undertaken by respondents in 1976. To enable crosstabulation it was necessary to derive a grouped variable named WORK.

WORK: This variable grouped the number of weeks employed into seven categories that attempted to differentiate between high levels of employment, but grouped low levels of employment. The results of these variables are given in Table 13.

Of all the tests conducted, only the oneway analysis of variance for blacks on the continuous variable WKSEMP was statistically significant. The results show that, on the average, non-veterans had more weeks of employment than

did veterans. Despite this fact, black non-veterans did not average a higher income, as determined in Table 4. This result is possibly due in part to the higher hourly rate by black veterans, as shown in Table 3. Other reasons for the statistically significant lower number of weeks of employment by black veterans is that they may encounter greater difficulties during the transition period from military employment to civilian employment than do white veterans. This finding would tend to be supported by the high re-enlistment rate of blacks in the Army [Moskos, 1979]. For blacks, security of employment, and the equal opportunity environment of the military, may be far better than that available in the civilian sector.

8. Mental Ability

IQ: Mental aptitude, as measured by the standard intelligence quotient score is given by the variable IQ. The IQ variable in NLS data has been derived from numerous tests and at times includes rescaled grade point averages, Kohen (1976). Thus, interpretations made from this variable are suspect and should be viewed with caution. For the cross-tabulation presentation, the standard format as derived by the NLS Center was used for each sample.

IQSTIN: This variable gives IQ scores grouped by population percentages into nine categories to produce a bell-shaped curve. Table 14 gives the results of the oneway analysis of variance and the other two statistical tests.

Taking the IQ values as given, it was found that both
the Chi-Square and Kolmogorov-Smirnov tests showed the given
distribution for veterans and non-veterans to be statistically
significantly different for whites but not for blacks for the
grouped data. However, the difference in means between vet-
erans and non-veterans for both blacks and whites was sta-
tistically significant. For blacks, on average, veterans
were four points superior to black non-veterans. The reverse,
however, held true for whites, with non-veterans being approxi-
mately 2.5 points superior to white veterans, on average.

9. Socio-Economic Status

SES: This is a socio-economic variable that has been
constructed by the NLS Center to incorporate the various
influences of the respondent's home environment. In particu-
lar, the socio-economic status (SES) index is comprised of
the following five indicators:

1. Father's occupation.

2. Father's education level/highest grade.

3. Mother's education level/highest grade.

4. Education of the oldest, older sibling.

5. Availability of reading material in the home.

The variable has been constructed to have a grand mean of 10.0
and a standard deviation of 3.0. A high index number would
indicate a favorable home environment in which the individual
would possibly have greater opportunity, and encouragement to
develop his talents. The range of the SES variable for the
sample was 2.1 to 15.8.

SESG: A derivation of the socio-economic status variable SES was necessary. SESG grouped SES into categories to present the crosstabulation format shown in Table 15.

An examination of Table 15 shows that for blacks, the veterans come from backgrounds that have a statistically significantly higher socio-economic index than for the black non-veterans. However, for whites the reverse is true, with veterans coming from statistically significantly less privileged homes. The Kolmogorov-Smirnov test shows that the two sample distributions do not differ. However, this is possibly due to the effects of too few categories. Categories were arbitrarily set to maintain cells with expected frequency counts of greater than 5. The significance of these results is that it confirms [Reaghard, 1980] studies in which he found the military was not representative of society. Reaghard indicated, as these results do, that the military had the better privileged blacks, but the less privileged whites.

10. Hours Worked Per Week

CJOBHRS: This is a variable which gives the average number of hours worked in a week by individuals in the sample as reported in the 1976 survey. The range for full employment began at 35, and extended as high as 105.

HOURS: To enable crosstabulation of the data a constructed variable, HOURS, was formulated by arbitrarily assigning eight categories. While it was thought appropriate to use a regular five hour interval for the first seven

categories, the low numbers above sixty hours per week made it convenient to group these together.

No statistical test proved significant in the black sample for difference between veterans and non-veterans. However, it was found that for whites all tests were statistically significant. Non-veterans worked, on the average, approximately one hour more per week than their veteran counterpart. These figures were significantly different at the .05 level, and are reported in Table 16.

D. EARNING FACTORS SUMMARY

Table 17 summarizes the variables and their levels of significance in the oneway analysis of variance, Kolmogorov-Smirnov and Chi-Square tests. Due to the arbitrary grouping of variables and the large sample size, the value of the Chi-Square for other than the dichotomous variables is to be accepted with caution. A closer examination of data distributions is generally well advised as individual judgment is required to evaluate better the data. The Kolmogorov-Smirnov test should assist this judgment by indicating if the veteran and non-veteran distribution for that factor differed radically in distribution. This is particularly important, where data are grouped for convenience into categories with no basic rationale. Most categories were assigned on the basis of ease of presentation and the aim of keeping expected cell counts greater than 5, or 80 percent of the table with

cells having expected frequencies greater than 5. This rationale enables some value to be placed in the Chi-Square statistic.

1. Blacks

An examination of Table 17 indicates that the veteran and non-veteran samples for both black and white have many significant dissimilarities. It would appear that for blacks, non-veterans have an advantage over black veterans in only greater tenure and weeks of employment. Black veterans, however, despite that disadvantage, command a significantly higher rate of pay per hour, and higher annual income from wages and salaries than black non-veterans. Other significant advantages that black veterans possess over black non-veterans, are higher levels of education, intelligence, and socio-economic family backgrounds. They also undertake more vocational training, and tend to reside in less rural areas. From this analysis, it could be inferred that the black veteran sample is generally superior to the black non-veteran group in most factors that contribute to employability, and income generation. The only two factors on which black non-veterans were superior to black veterans was in tenure, and weeks of employment. This non-veteran superiority in tenure, and weeks of employment, is one that should be expected. Loss of tenure, and employment, by veterans, would be a natural result of their military service, and the transition employment period into the civilian sector.

2. Whites

For whites, the data would indicate that white non-veterans have employment advantages over veterans with regard to education, intelligence, tenure, and family socio-economic status. White veterans, however, are favorably situated with regard to marriage, health, vocational training, and age. Moreover, white veterans tend to reside more often in SMSA areas helping them have greater access to employment opportunities.

The most common, and usually the ultimate measure of employability, is the "price" employers are willing to pay. Accepting this as an appropriate objective measure, results indicate white non-veterans earn significantly higher incomes than do white veterans.

E. CONSTRUCTED EARNINGS PROFILES

Unfortunately, the limitations of these results are that the data are cross-sectional. This means we are taking a "snap shot" of respondents as to their earnings, and earning attributes as reported in the 1976 survey. These data limitations do not make it possible to determine disadvantages or benefits accruing to individuals as a result of their military service over time. In fact, this would only be possible if the analysis had been conducted longitudinally.

In an attempt to rectify this deficiency and give some possible indication of longitudinal benefits, hourly wage

rate, and annual income have been disaggregated by age and plotted graphically. For this graphical presentation to represent a segment of life-cycle benefits, it is necessary to make two assumptions:

1. The distribution of earning factors between large groups is not affected by time or is proportionately time affected. To further clarify this point it is assumed that attributes like IQ do not change distribution in a large group regardless of age. While tenure, additional education, and training, health, marriage, incomes, etc., are time affected, but in a proportionate sense. For example, this implies that the distribution of attributes of the current 28 year olds in the population will be the same as the current 32 year olds, in four years time. Similarly the current 28 year olds had an identical distribution of earnings attributes as possessed by the current 24 year olds four years previously.

2. Economic factors like inflation, recession or industrial disputes, are held constant.

It is appreciated that the first assumption is a tenuous assumption for the veteran group. In particular, not only have veterans been selected because they met some basic selection criteria, but historical circumstances have possibly varied these selection standards. Historically, this era saw the draft, draft avoidance, lottery selection, and voluntary recruitment. These factors possibly bias those in the veteran group in relationship to the most influential or prevalent factor present at the time of enlistment.

97

There is no way of controlling for the second assumption except by using the term "ceteris paribus". However, despite these limitations the constructed earnings profiles may give us some insight into the time dependent nature of any veterans earnings premium. Using the criteria as given, Figure 5 and Figure 6 have been produced from the information given in Tables 18 and 19. Figure 5 gives hourly pay rate by age (time), while Figure 6 gives annual income by age (time). Due to the low number of black veterans in many age groups it was considered inappropriate to produce that curve.

It can be seen from Figure 5, hourly wage rate by age, that white non-veterans demand a higher hourly pay rate than veterans in eight of the eleven reported age groups. Similarly in Figure 6, income obtained by non-veterans is consistently higher for all age groups except for the 32 year olds. For black non-veterans, the curves show a remarkable consistency of no increase over age. These graphs raise many interesting questions as to the qualities and reasons that contribute to the apparent disparity in wages between veterans and non-veterans, blacks and whites. However, the interaction between factors to give these financial differentials is complicated and more statistically sophisticated techniques are required to identify which factors contribute to income, and the extent of their contribution. This type of analysis is beyond the powers of the descriptive statistics produced in this chapter. In the next chapter multivariate analysis is

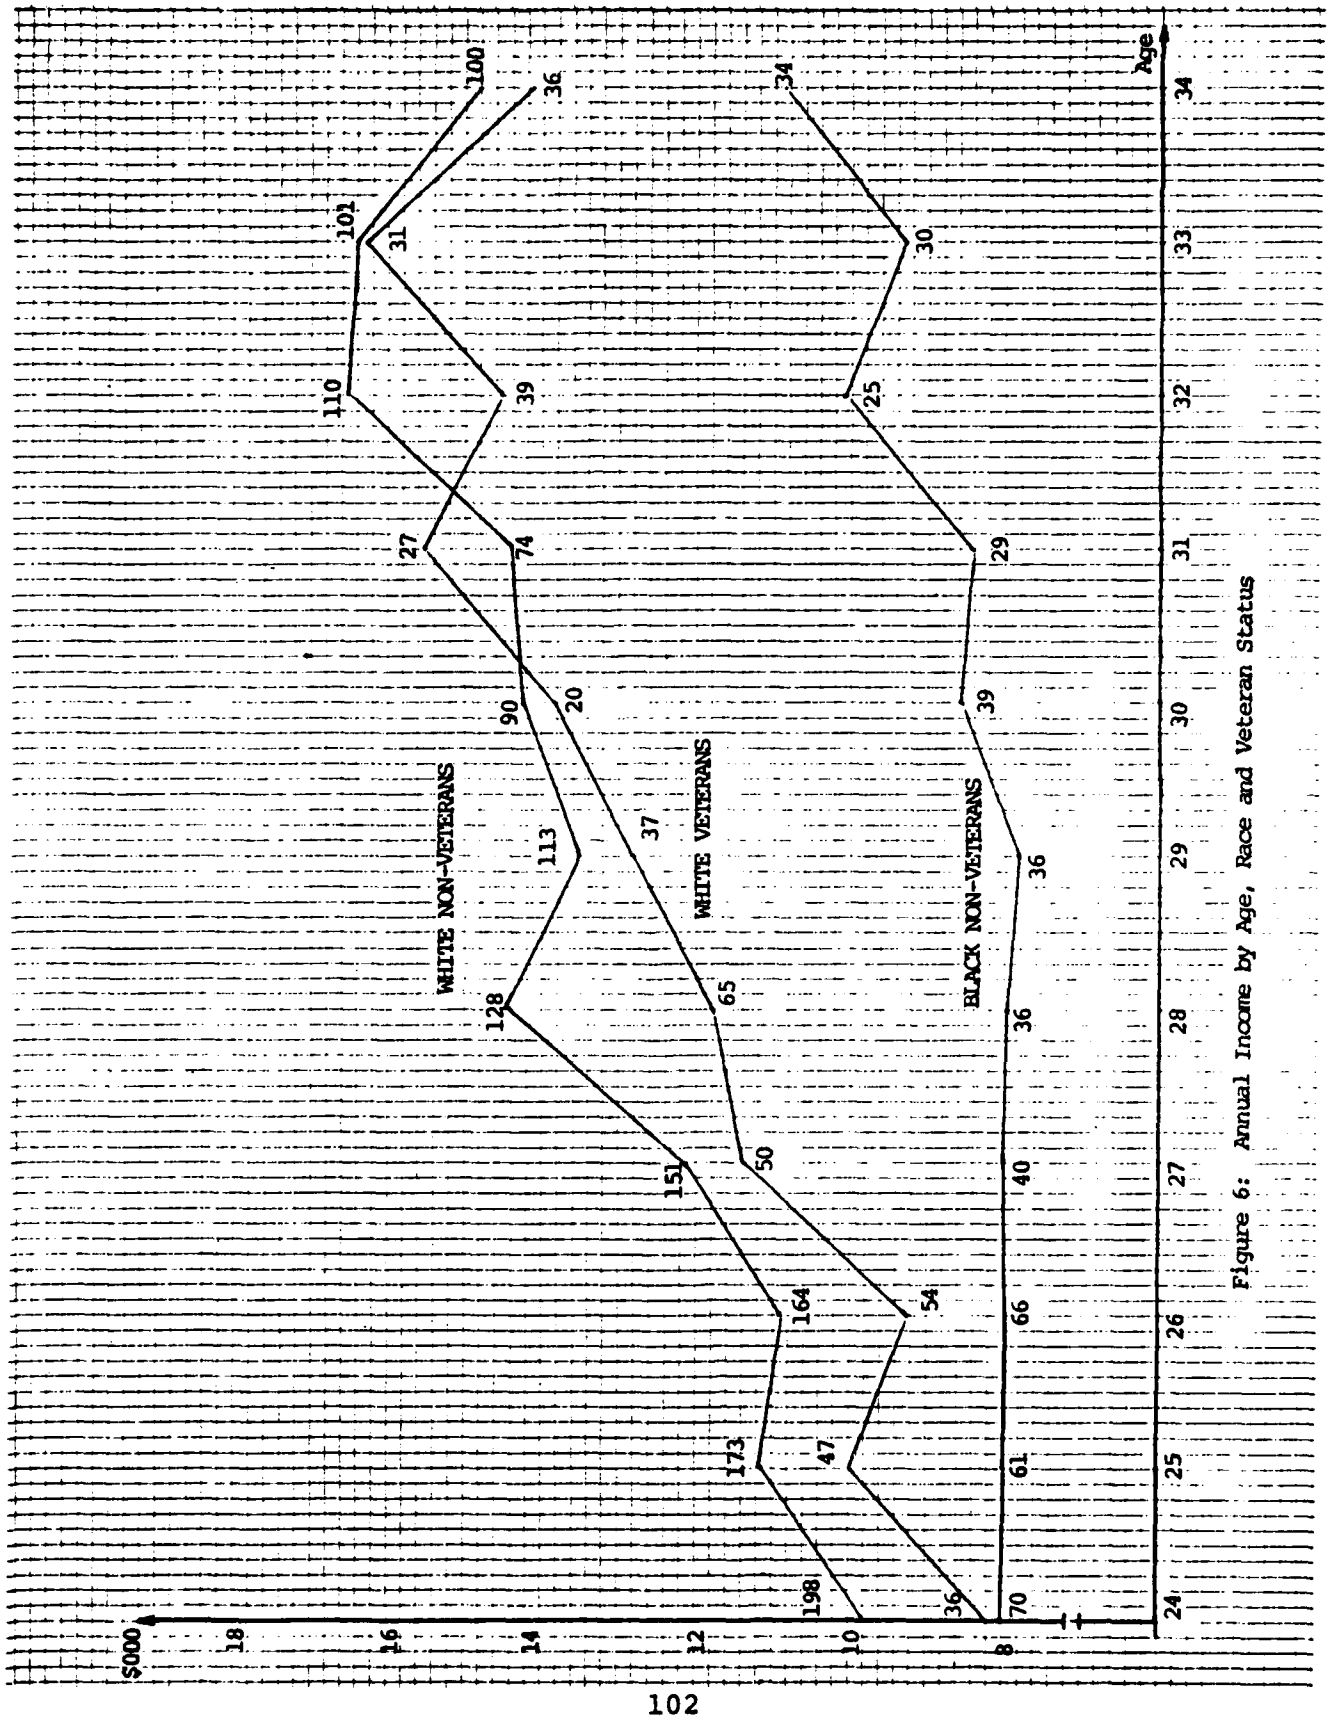

Figure 6: Annual Income by Age, Race and Veteran Status

conducted to control for the variability of each factor or attribute simultaneously. This methodology enables not only identification of those attributes that contribute or detract from earning capacity, but also the extent of their influence.

F. SUMMARY AND CONCLUSIONS

In summary, it would appear from the factors described and statistical analysis conducted, that black veterans display employment and income generating qualities that are superior to their non-veteran counterparts. However, for whites, the reverse is generally true, as non-veterans show superior qualities to veterans. Due to the range of variability on factors in the sample of veterans and non-veterans, it is not possible to attribute "veteran status" with employability or income enhancing qualities. If it is assumed that the sample of black and white veterans, as presented by this data, is representative of all blacks and whites who were enlisted or drafted during the 60's and early 70's, three conclusions can be drawn.

1. The military has recruited the better quality blacks but the poorer quality whites.

2. The methods of military manpower procurement used in this era failed to produce a military that was representative of society.

3. The average income by age, generated by white veterans when compared to white non-veterans, is consistently less.

The first two of these observations are supported by Reaghard (1980). He found black veterans were from higher socio-economic indexed families and displayed superior qualities to their civilian counterparts. For white veterans, however, the reverse was generally true. Moreover, Reaghard concluded the draft did not produce a military representative of society, while Moskos (1979) stated that conclusion about the All Volunteer Force. This raises the interesting question of how to achieve a representative military, which unfortunately exceeds the scope of this study. An attempt to precisely identify and quantify the contribution, if any, of veteran status will be conducted in the next chapter.

V. REGRESSION ANALYSIS WITH VETERAN STATUS

A. INTRODUCTION

The second hypothesis was to ascertain whether earnings received by those who had completed a tour of military duty were different from those earned by individuals who choose not to undertake military service. Formally stated,

H_0 = Military service is no different from obtaining work experience and training in the civilian sector when measured by income received in post-service employment.

As detailed in Chapter III, there was considerable variability in earnings attributes between the veterans and non-veterans in the sample. To simultaneously control for this variability, multiple regression analysis was utilized. By employing the multiple regression technique, it was possible to produce a predictive or explanatory model of earnings, as well as identify the comparative strengths or influences of the variables.

B. THE MODELS

Two regression models were constructed to test the hypothesis. Both models used similar explanatory variables, but each employed different dependent variables. Model 1 used as a dependent variable hourly pay rate in an attempt to

capture a "potential" rate of pay, while model 2 used as a
dependent variable total income from wages and salaries.
Each model is typical of the Mincer (1974) human capital esti-
mating equation which is formally expressed by:

$$W = e^{a_0 + a_1 V_1 + \sum a_n EF_n}$$

where W is the dependent variable, a_0 is the constant, V
is a dummy variable assuming the value zero for non-veterans
and one for veterans, and $\sum EF$ is the sum of all the other
earning factors. This equation is more commonly expressed
as:

$$Ln(W) = a_0 + a_1 V_1 + \sum a_n EF_n$$

The use of the semi-logarithmic form is common in studies
utilizing the investment in human capital approach. It is
primarily used to reduce the positive skewness found in most
earning distributions. By reducing the skewness, it is possi-
ble to enhance the statistical fit of the equation. That is,
the amount of explained variation, as indicated by the R^2 for
the prediction equation, is greatly increased. In addition,
the resulting coefficients of variables from this equation
enable two useful interpretations:

1. The expected percentage change in the dependent
    variable that would occur if one unit change in
    an explanatory or independent variable was
    implemented.

2. The rate of return accruing to the acquisition of
    an additional unit in the explantory or independent
    variable.

One aspect of the construction of the equation possibly requires further explanation. Work experience, which is derived by subtracting years of schooling plus five years of pre-schooling from age, was not used as a variable, i.e.,

Work experience = (Age - (Years of schooling + 5)).

This is a departure from Mincer's traditional earning equation, but the reasons for this departure were two-fold. First, Binder (1976) had found the work experience estimation to be unsuitable for members who are subject to broken work experience or labor market activity like "women", and "military" personnel. Secondly, when a Pearson correlation was computed using a derived work experience variable, work experience was found to be highly correlated with age (r = .76), and years of education (r = .63). This high level of intercorrelation or multicollinearity between the independent variables would increase the variance of the estimate and reduce the reliability and the significance of the coefficients of the variable. Moreover, the usefulness of using an explantory varible's coefficient that is subject to multicollinearity to indicate percentage changes or rates of return, as explained earlier, would be statistically incorrect.

C. THE VARIABLES

Two variables that were detailed in Chapter IV were not utilized in this regression model. These two variables were mental ability (IQ) and socio-economic status of the respondent's

parental home (SES). There were three reasons for the dele-
tion of those variables from the analysis.

First, it was found, as expected, that both IQ (r = .46)
and SES (r = .55) were highly correlated with education. This
multicollinearity would thus detract from the accuracy and
predictiveness of the education coefficient. As education is
a key determinant of earnings, it is useful to employ its
coefficient to estimate rate of return or percentage change
in income attributable to an additional year of education.
This would not have been possible if SES and IQ had been
retained.

Second, both IQ and SES were variables that were con-
structed by the NLS center. The problems of collection and
normalization of the collected data were considerable. Con-
sequently, many cases failed to have these data recorded. As
the regression equations used only cases that had responses to
all variables, the reduction in the usable sample size was
considerable. When SES and IQ were included, the usable sam-
ple for blacks, which was 503 (92 veterans and 411 non-veterans),
fell to 164 (36 veterans and 128 non-veterans). For whites,
the sample size was reduced from 1578 (363 veterans and 1215
non-veterans), to 1153 (291 veterans and 862 non-veterans).

Third, Cohen (1975) suggests that as a prudent rule of
thumb the number of regressors used should be limited to not
more than one fortieth of the sample size. As there were
twelve regressors in model 2, this would require a minimum
sample size of 480. It can be seen that the black sample only

just meets this criterion. This would not have been possible with the inclusion of intelligence and socio-economic status in the model. Variables used in the models are given below and summarized in Table 20.

1. Dependent Variable

As mentioned earlier, two earning measures were employed. First, model 1 used as a dependent variable LOGPAY. This variable was the natural logarithm of hourly rate of pay, HRLYPAY, as defined in Chapter IV. That is, LOGPAY = Ln(HRLYPAY). Equation 1 attempted to ascertain those factors which simultaneously affect hourly earnings of veterans and non-veterans. The structure of the equation was designed to capture more of the "potential" earning power of individual factors. It was hoped, therefore, to predict an hourly rate of pay that an individual may receive without regard to the number of additional financial fringe benefits he may receive due to tenure and special bonus payments.

Model 2 used as a dependent variable LOGINCO. This variable was derived by taking the natural logarithm of annual income or total wages and salaries received in 1976. That is, LOGINCO = Ln(Y). The structure of the equation was to identify the effects of the explanatory factors as detailed in Chapter IV on total earnings from all sources, received from an employer.

2. Independent Variables

The independent variables employed in each model are given in Table 20. These variables are constructed and

TABLE 20

REGRESSION MODELS

WKSEMP	Weeks of employment in 1975-76	X	X
AGE76	Age in 1976	X	X
CJOBHRS	Hours worked per week		X

defined exactly as found in Chapter IV. One independent variable, TENSQ, did not appear in Chapter IV. This variable is defined as the square of tenure, and has been introduced to account for the diminishing returns one would expect to find with increased length of employment with the same employer. It is doubtful whether any employment situation exists where salary is completely related in direct proportion to length of service. Thus TENSQ is introduced to capture some of the diminishing effects of tenure over time, while TENURE accounts for the advantages of increasing length of service with an employer.

The only variation between model 1 and model 2 in independent variables is that model 2 included average hours worked per week. This was necessary as hours worked have an obvious and direct influence on annual income, and therefore its effect needed to be controlled.

3. Variable Correlation

To ensure that the correlation between variables was known and detailed, Pearson Correlation Coefficients for the multiple regression equations run are shown in Table 21 for blacks and Table 22 for whites. Except for tenure squared, TENSQ, which is obviously highly correlated with tenure, there was no other variable that had a correlation coefficient that exceeded .40.

4. Variable Assumptions

In running the regression equations. it was assumed that the variables for age, education, tenure, hours, and

weeks of employment approximate continuous varibles. Varia-

bles for vocational training, veteran status, marriage,

health status, geographical regions, and SMSA retained their

dichotomous nature, and were introduced as dummy variables

into the equation.

D. RESULTS OF THE BASIC MODEL

Both models were run for each racial grouping. Table 23

details the results obtained for blacks, while Table 24 gives

the results for whites. Generally, it was found that:

1. All equations were significant at the .001 level of
    significance.

2. The models gave greater R^2 values for blacks than for
    whites.

3. Model 2 was superior to model 1 when tested by goodness
    of fit, or ability to explain earnings variance. That
    is, model 2 consistently produced a larger R^2 than did
    model 1.

4. As one would expect, both poor health and residence
    in the South detracted from earnings. Similarly,
    as expected, marriage, residence in a SMSA, and
    vocational training gave positive returns to earnings.
    These five factors proved to be consistent in each
    equation regardless of model or race.

5. The models showed particular factors had greater or
    lesser significance due to the influence of race.

The last result should not be surprising. The analysis

in Chapter IV had indicated that the black veterans were

socio-economically superior to black non-veterans, while the

reverse was true for whites. It was therefore to be expected

that earning attributes had different degrees of influence in

the equation due to race. For this reason, it is appropriate

to discuss the results by race.

1. Blacks

Model 1 had a statistically significant equation that gave an R^2 of .34. Except for weeks of employment, age, and veteran status, all other coefficients in the equation were significant at the .05 level of significance or higher than the .05 level of significance. The two most influential factors were education and tenure. Both education and tenure gave a rate of return of four percent to individuals for each additional year of schooling, or tenure possessed. In contrast, veteran status made only a total contribution of two percent, or, on the average, eight cents per hour ($4.66 x .017).

Model 2 for blacks was better than model 1, in that it could explain 54 percent of the variance in annual income. (R^2 = .54.) However, this model also had three factors whose coefficients were not significant at the .05 level: age, vocational training, and veteran status. Once again, education with a rate of return of six percent for an additional year of schooling and tenure with a rate of return of five percent for an additional year of service with the same employer, were among the most influential factors. As expected, weeks of employment also gave a percentage change of three percent for an additional week of employment. Veteran status, however, had a negative 5.3 percent return, which for the average veteran would mean a loss of $450 on his annual income ($8484x - .053).

From the above analysis it is apparent that for blacks, veteran status has no positive influence in the generation of income. In fact, veteran status has a possible negative effect, due to loss of income through loss of tenure, and weeks of employment. Chapter IV had indicated that veterans had on the average, 1.8 years less tenure and 2.5 weeks less employment per year than non-veterans. These figures were statistically significant at the .05 level.

2. Whites

Model 1 for whites had a statistically significant predictive equation at the .01 level of significance, and an R^2 value of .30. An examination of Table 24 shows that all explanatory variable coefficients except veteran status were significant. Here again, education, and tenure were also very influential. A rate of return of four percent accrued to members for an additional year of schooling or tenure possessed. Veteran status, although positive, had a less than one percent return, or an average contribution of four cents per hour, to hourly wage rate ($6.19 x .006).

For whites, Model 2 was superior to Model 1. Not only did model 2 have a far higher overall F value for the equation, but R^2 increased to .47. In addition, all explantory variables were significant at the .01 level, except veteran status. Factors that proved to be most influential in the determination of income were; weeks of employment, education and tenure, with respective returns of 3, 5, and 7 percent

120

for each additional unit possessed. Veteran status on the other hand had a negative influence of $447 per year for the average white veteran ($12,769x - .035). These results would indicate that veteran status fails to contribute positively towards earnings.

To test whether the effects of veteran status diminish as the time period since the member last served lengthens, Model 2 for whites was run for ten periods. That is, groups of veterans who had been in the civilian sector for only one year, two years, and so on, were consecutively deleted. It would appear from these results, which are to be found in Table 25, that the size of the negative coefficient for veterans does not diminish until after the seventh year. Thus, the average veteran can expect financial loss due to serving in the military for periods in excess of seven years after his service.

Before leaving this section, it is appropriate to comment on the fact that in no equation did the coefficient for veteran status prove to be statistically significant. This in no way reduces its importance in the prediction equation, as the total equation proved to be significant as measured by the F test, at the .01 level of significance. However, the results of using an individual coefficient that was not significant to predict individual returns accruing to that variable, is possibly subject to error.

To test if veteran status made any contribution to the equations, hierarchical stepwise regression was conducted.

It was found that veteran status had a significant F value until tenure or weeks of employment entered the equation. These two factors impact via correlation of tenure with veteran status, and tenure with weeks of employment. Therefore, when the forward stepwise regression is utilized those variables that have the most significant addition to explained variance enter first. Thus, as both tenure and weeks of employment had a greater contribution to explained variance, they enter the equation prior to veteran status, and are credited with the shared variance with veteran status. That is, the standard F test for a partial regression coefficient gives credit to each variable only for its incremental contribution after all the other independent variables have been introduced in the equation. Veteran status had little to offer to explained variance when it entered the equation last.

E. SUMMARY

This chapter tested the hypothesis that work experience and training gained by members who undertook military service is no different in its effect on income than for members who gained work experience and training in the civilian sector. The two models that tested the hypothesis produced conflicting results. Model 1 produced positive returns to veterans, while Model 2 produced negative returns to veterans. However, Model 2 gave a better explanation of variance or overall better goodness of fit. In addition, Model 2 predicted total annual income, which is a better measurement of economic well being.

Thus, it is possible to reject the null hypotheses and conclude that veteran status is detrimental to future earnings.

These results further highlighted the plight of veterans. Education, tenure and weeks of employment which do not favor white veterans have high rates of return. In particular, it would appear continuous civilian employment assists future income generation more than an enlistment period in the military. The disruptive effect of military service apparently creates a penalty on future earnings of veterans regardless of other attributes possessed.

This analysis would lead one to conclude that the military, as a method of investing in human capital, is ineffective. Better returns are possible if individuals invest in additional years of schooling, or specific, and general training offered by firms who give employment security.

However, this analysis did not identify those members who enlist to avoid the high unemployment rates prevalent among youths. Even though veterans in 1976 appear to suffer financially, longitudinal studies may reveal that civilian members with similar attributes suffered high levels of unemployment during earlier periods in their life. Thus, the security of military employment for veterans may compensate for part of the post service losses in income. This is one area where insufficient research has been conducted and would be necessary prior to conclusive statements of lifetime benefits can be made. For policy makers, this analysis would suggest the best possible way of diminishing the effects of veteran service

is to provide extra education during and immediately after military service. Other methods that would be appropriate are tax cuts for veterans or employers of veterans.

In summary, the conclusions that can be drawn from these results are:

1. Veteran status can not be said to have any positive influence on post service earnings. This cross sectional analysis would indicate that work experience and training gained through military service is not superior to work experience and training obtained in the civilian sector. In fact, it is possible that veteran status could further detract from future income, due to losses in tenure, and employment. These factors seem to be related to military service, and the transitionary period of employment on return to the civilian sector.

2. Youth contemplating enlisting in the military service for other than careerist reasons would be better advised to seek additional years of schooling, or obtain jobs in which tenure has positive influences.

This result would confirm recent studies by Bolin, Hess and Little (1980) who analyzed cross sectional data of samples from the NLS youths survey utilizing 1969 and 1971 data. Their conclusions were that short run economic benefits to having served in the military were negligible.

The next chapter attempts to identify those patterns in military service that tend to influence returns in post service earnings. This analysis should assist in determining

which veterans lose the least as a result of their military
service.

VI. SPECIFIC MILITARY INFLUENCES ON POST SERVICE EARNINGS

A. INTRODUCTION

This chapter examines the influence on post-service earnings of various methods of participation in military service. An individual contemplating military service has various options he may exercise. These options vary from the selection of the branch of service and the enlistment period he desires, to specifying particular skills and training he wishes to undertake. Due to the draft many of those in the 1976 sample did not have freedom of choice over all of these options. Many members, however, did have some discretion over the type and length of training. No effort has been made in this study to identify specifically the various types of training undertaken. It is assumed that length of the training generally would indicate a selection process related to ability. Thus, those who received longer periods of training are assumed to have been chosen because they were better able to perform jobs requiring greater skill and expertise.

By studying whether specific military experiences enhance or diminish post-service earnings, policy makers may be able to determine appropriate compensation levels. Policies may need to be established that vary enlistment periods to obtain economic returns to the military, depending upon the particular training given to individuals.

B. THE MODELS

Two regression models similar in design to those used in Chapter V were employed. The same dependent variables were utilized, but military specific independent variables were also introduced. The actual equation used was the semi-logarithmic form expressed by:

$$\ln(W) = a_0 + a_1 N + a_2 A + a_3 M + \sum a_n EF_n$$

where W is the dependent variable, a_0 is the constant, N, A, and M are dummy variables indicating Navy, Air Force or Marine Corps. Finally, $a_n EF_n$ were either specific military or other earning factors in the equation. All of the advantages of using the logarithmic form as mentioned in Chapter V are still relevant. The exceptions to this statement are the service variables, which required a special binary formulation.

C. THE VARIABLES

The dichotomous variables used in Chapter V were not employed in these models. It was thought that the influence of those particular variables would detract from simplifying, and focusing attention on the military specific variables. Moreover, the number of regressors was still ten, but the sample size was only 394. Consequently it was considered prudent to keep Cohen's (1975) rule of thumb, with regard to a one to forty ratio of regressors to sample size.

Other variables deleted from this model were age and the square of tenure. Age was deleted due to its high correlation

with the variable that expressed the period of time since the member last served in the military (LASTMIL). The reason for this high correlation was because 70 percent of all service members enter at an age under twenty years. In addition, 78 percent do not serve longer than their first term [Binkin, et al., 1979]. Thus the majority of youths join the services between 18 and 20 and leave between 22 and 24 years of age. Any variable that measured the period of time since the member last served was highly age related. The square of tenure was deleted because of the relatively short period of tenure reported. Veterans in the sample averaged only four years tenure, which was considered insufficient to incur diminishing returns.

The dependent variables utilized in the regression analysis were hourly rate of pay and annual income. These variables retained the same definition as detailed in Chapter IV. Other variables retained for the military specific regression models were the independent variables for education, tenure, and weeks of employment. From the experience gained in Chapter V, it was obvious that these three independent variables have considerable influence in the determination of income. Their retention seemed essential if the influence and the variability of these factors were to be controlled. These three independent variables retained an identical format, and definition as detailed in Chapters IV and V.

New explanatory variables introduced into the regression equation to cover specific military influences that required

controlling were branch of service, race, and military specific continuous variables.

1. Branch of Service

A set of three dummy variables was created by treating service in the Navy, Air Force, and Marine Corps as separate variables. By assigning the value of one, for its presence, and a zero for its absence in each of these three military categories, it was possible to account for service in all four branches. Thus a member who belonged to the Navy would be scored one on the variable representing Navy, but zero on the variables representing Air Force or Marine Corps. The influence of Army service was included in the constant value. This detracts from the intuitively appealing individual coefficients for each service, but was essential to produce the model following the techniques recommended by both Cohen (1975) and Nye (1975). Table 26 details the method of binary coding.

2. Race

It had been anticipated from Chapter V that the sample for veterans should have numbered approximately 500. However many veterans failed to respond to specific military questions and the sample was reduced to 393. Only cases having responses to all variables were considered in the regression equation. There were 74 black veterans and 393 white veterans in the sample analyzed. A dummy variable was created for RACE. Blacks were assigned the value zero and whites the value one.

TABLE 26

BINARY CODING OF BRANCH OF SERVICE

| | Names of Dummy Variables | | |
TYPE OF SERVICE	NAVY	AIR	MARINE
Navy	1	0	0
Air Force	0	1	0
Marine Corps	0	0	1
Army	0	0	0

3. Military Specific Variables

Three continuous variables specifying type of military
service were constructed to capture the effect of various
patterns of participation in the military.

a. MILTIME

This variable was constructed to gauge the effect
of the various periods of time spent in the military. The
range extended from 24 months to those who had completed 8
years of service. As most services have varying terms of
enlistment, one would have expected to find specific periods
of time spent in the military correlated with a particular
service. This, however, was not so, the highest correlation
being $r = .03$ for the Navy.

b. MILTRG

Human capital theory proposes that time spent in
formal training should enhance productivity and thus favorably
influence the "price" employers are willing to pay for an
individual's labor. This variable accounts for the months of

131

formal training that were additional to "boot camp" or basic training. Months of training, according to human capital theory, should enhance future earnings if the member chose to enter a comparable civilian occupation. Training undertaken may also indicate to an employer that an individual possesses attributes that are conducive to additional training. This last statement is confirmed by Norrblom (1976) who found that the more able servicemen were selected for training.

c. LASTMIL

To indicate the number of years since a respondent completed his military tour, a variable was constructed by subtracting his year of discharge from 1977. This is an important variable because the longer a veteran has been out of the service the greater the opportunities he has had to:

(1) Take advantage of the G.I. Bill benefits.

(2) Search for a job that optimizes his attributes.

(3) Increase his tenure with an employer, and obtain those benefits that accrue to tenure.

It was therefore necessary to control for these effects in the regression equation. Table 27 gives a summary of the dependent and independent variables used in each of the regression equations.

The main purpose of this chapter was to use multiple regression analysis to identify the effects of specific patterns of participation in the military. To give the regression results a more meaningful perspective, distribution characteristics of variables have been produced. Table 28 gives

Scheffes Test: No two groups are significantly different at the .05
level

the means and standard deviations of each variable. In addition, the means by branch of service are tested to determine if they are significantly different, using the SPSS oneway analysis of variance program. The means were tested for posteriori contrasts by the Scheffe technique. The Scheffe test uses a single range value for all comparisons, not just pairwise comparisons. Thus, it is much stricter than other tests and is exact, even for unequal group sizes [Nye, 1975].

The format of Table 28 is standardized to give the variable name, and the mean, standard deviation, and sample size for each of the four branches of service. Caution should be used in interpreting these results as they have not been broken down by race. Thus the Army, which had a 35 percent black participation rate in its sample, would possibly report a lower hourly pay rate than say the Navy with a sample containing only 9 percent blacks. Following these statistics the results of the Scheffe test are given.

D. RESULTS

Table 29 gives the results of Model 1 and Model 2. The Pearson correlation coefficients for both models are detailed in Table 30. Generally speaking, Model 2 is the superior model using goodness of fit as the test criterion. While both models produced statistically significant equations at the .01 level of significance, Model 2 had an R^2 of .54 compared to Model 1's R^2 of .31. Both models give some interesting insights into the pattern of military participation that enhances earnings.

1. Model 1

This model used hourly rate of pay as the dependent
variable. As it was required to binary code the branches of
service and use the Army variable as a reference category,
the coefficients for the services require an additional com-
putation to give the comparative value of a particular branch
of service. Since the value attributable to Army is contained
within the constant, it is best to assume that this is the
Army value and subtract or add the other service   'cients
from this value. Using this methodology the coeffit   ; for
each individual service are;

   a. Army: 5.01

   b. Navy: (5.01 + .08) = 5.09

   c. Air Force: (5.01 + .05) = 5.06

   d. Marine Corps: (5.01 - .09) = 4.92

On a comparative basis, it can be seen that military service
in the Navy is the most profitable when utilizing hourly pay
as the dependent variable. As all other variables are con-
trolled by the regression analysis, it is possible to calculate
the comparative percentage advantage associated with service
in a particular branch of the military. For example, the
percentage advantage of service in the Navy over the Marine
Corps, in relation to hourly pay, is 19 percent. This is
calculated by computing the returns to Navy service, subtract-
ing the returns to the Marine Corps, and dividing the resulting
amount by returns to the Marine Corps,

139

$$\frac{e^{5.09} - e^{4.92}}{e^{4.92}} = .185 = 19\%$$

As expected, education, tenure, and weeks of employ-
ment had positive coefficients. LASTMIL also had a positive
coefficient indicating the longer the period a respondent had
been in the civilian labor market, the greater would be his
pay. We find, however, a small negative coefficient for the
amount of time spent in the military (MILTIME). Military
time, it would appear, detracts from productive time spent in
adjusting to the civilian labor markets.

MILTRG, which controls for the months of training re-
ceived by an individual has a small negative coefficient of
-.005. This result is totally against intuition and economic
theory. As Model 2 also gave a negative coefficient to mili-
tary training, a discussion on this aspect will be delayed
until an examination of that model has been conducted.

In summary, Model 1 would suggest that a member enter-
ing the military with no particular service preference, would
choose the Navy, Air Force, Army and Marine Corps, in that
order, to optimize on his future hourly wage rate. He would
choose the minimum enlistment period and attempt to improve
his general level of education while serving, rather than
undertake specific military training.

2. Model 2

The dependent variable in Model 2 was annual income.
As stated earlier, Model 2 was superior to Model 1 in that it

gave a better explanation of the variance in total earnings.
The "F value" for the resulting equation was also consider-
ably higher. Moreover, a focus on total earnings would seem
more appropriate if one is to discover an individual's status
achievement in terms of personal security, and total economic
well being.

As the value of the Army was contained within the
constant, it was again necessary to calculate individual
service coefficients. These coefficients computed to:

a. Army: 6.09

b. Navy: (6.09 - .09) = 6.00

c. Air Force: (6.09 + .06) = 6.15

d. Marine Corps: (6.09 - .07) = 6.02

It can be seen that there was a change in the order of returns
to service in a particular branch of the military. Air Force
moved to first place with Navy to last place. It would appear
that while Navy personnel have the potential to earn higher
hourly wages, they fail to actually reflect that advantage in
total earnings. As both models used and controlled for the
same independent variables, the only conclusion is that Navy
members do not receive tenure based gratuities and bonuses.
An examination of Table 21 shows Navy had the lowest, but not
significantly different, length of tenure. However, if this
figure had been disaggregated by race it would have possibly
proved significant. The basis of this argument is found in
Chapter IV, where it was shown that black veterans had an
average tenure of 3.58 years compared to white veterans with

4.47 years. The very low percentage of blacks in the Navy should have resulted in a relatively higher tenure for Navy personnel. However, this result failed to materialize. Consequently it is possible to conclude that the lower reported incomes of Navy personnel may be the result of tenure related bonuses which they do not receive.

Using the methodology developed in Model 1, it was found that the average Air Force veteran obtains a 16 percent income advantage over the average Navy member.

$$\frac{e^{6.15} - e^{6.00}}{e^{6.00}} = .161 \approx 16\%$$

Marine Corps members however, only have a two percent advantage in annual income over Navy personnel;

$$\frac{e^{6.02} - e^{6.00}}{e^{6.00}} = .020 \approx 2\%$$

When race is examined, white veterans are found to have a 19 percent earnings premium over black veterans. Education, tenure, and weeks of employment, as anticipated, had high positive returns of six, three, and four percent, respectively, to each additional unit possessed of those variables.

Time since active duty gave approximately a three percent return on each extra year since discharge. As time of service became relatively more distant, one would expect that the effects of service life diminish as veterans integrated closer into society. LASTMIL in the equation, however,

may also be capturing some of the effects of age and experience on earnings. As explained earlier, age was highly correlated with LASTMIL. Age/earning profiles which show increasing income over time (age), as produced in Figures 5 and 6 and as developed by Hanoch (1967), would support this reasoning.

Time spent in the military, MILTIME, gave a positive coefficient of .0005, while months spent in additional training, MILTRG, gave a small but negative coefficient of -.0002. Both coefficients could be assumed to be zero as the size and the sign would not be statistically significant. It is of interest to note, however, that these results are similar to those found by DeTray (1980). DeTray in part of his analysis found:

1. The actual period of military service undertaken "neither improves nor worsens civilian wages."

2. "Training received in the military seems to lower civilian wages."

While the first results can be accepted, the second, although small, tend to deny human capital theory. DeTray separated out veterans who said they used military training on their civilian jobs. He still found that trained veterans did not command significantly higher wages than other similar individuals. DeTray's results for military training indicated a negative return of approximately 9 percent. Suggestions for this economically irrational result offered by DeTray are:

1. "Those who received training in the military may differ from those who did not in inate and unobserved ways that lowered their market productivity." DeTray

suggests that possibly veterans without training are
not an adequate control group against which to assess
the wage rates of veterans who receive training.

2. Those who receive training in the military may
   initially receive lower wages but may later have
   wages that increase at a quicker rate over the
   passage of time.

It is the author's opinion that those with low levels

of formal training, e.g., clerical worker, cooks, storemen,

drivers, etc., have readily marketable skills that are experi-

ence, age, and actual job performance related for payment.

Those who receive high levels of training are usually special-

ized into areas that are military specific and have little

civilian comparability. Another possible reason is civilian

organizations have already "grown" their own highly skilled

workers. Veterans have difficulty entering the market at

their skill level unless that particular field is expanding

rapidly. As a multivariable approach was utilized in an

attempt to control for the effects of "other variables" it

is believed the results obtained give a good indication as to

the returns veterans may anticipate as a result of their

pattern of military service.

E. SUMMARY

The results from this chapter would indicate that the Air

Force is possibly the best service to join if post-service

earnings are used as the measurement criterion. In addition

it would appear that potential recruits should be advised to

enlist for one short tour of duty. While in the service he

should undertake general training and use the service system to improve his level of education.

Possibly the most surprising aspect of the results were the returns to training. In 1976 the military devoted 80,000 man years of trainee time, at a cost of $2 billion in initial speciality training [Gay, 1979]. It would appear from this analysis that those typically huge expenditures of time and money in military training have failed to enhance veteran earning power in subsequent civilian employment. The loss of civilian experience and training does not appear to be compensated for by military work experience and training.

For policy makers these results would indicate a need to publicize the values of service training. Certificates of training undertaken with its equivalent qualification should accompany honorable discharges to facilitate the return of a veteran to the civilian sector. In addition, short term enlistments, 2 years, with post-service education benefits for occupations that are military specific, e.g., infantry, could be offered. This may be an attractive alternative to young men who cannot afford a college education, but do not want to invest four years of their time in the military.

VII. SUMMARY CONCLUSIONS AND RECOMMENDATIONS

It's Tommy this an' Tommy that, an'

"Tommy, wait outside,"

But it's "Special train for Atkins" when

the trooper's on the tide.

It's Tommy this an' Tommy that, an'

"Chuck, him out the brute!"

But it's "Saviour of 'is country" when

the guns begin to shoot.

Rudyard Kipling 1865-1936

A. SUMMARY

The value of a tour of military duty as a method of in-
vesting in human capital was analyzed in this thesis. Con-
clusions presented in this section are based on information
gathered in 1976 by a national longitudinal survey of young
men aged 14 to 24 in 1966.

The first part of this study reviewed the principles of
Human Capital Theory. Using the concepts of specific and
general training as a method of accumulating human capital,
it was predicted that those who undertake military service
should receive earning premiums for this training in their
post service occupations.

Eight previous studies that have examined returns to
veterans in post service employment were reviewed. Only two

of the studies, Cutright (1972) and Bolin et al., (1980), came to the conclusion that military service provided no post service premiums. Studies by sociologists, Browning et al., (1973), Lapreato et al., (1972) and Martindale et al., (1979) concluded that for minority groups, military service provides a "bridging environment" giving veterans substantial advantage in their post service earnings. The literature review highlights the fact that results are highly dependent upon the samples investigated and methodology utilized. Thus, similar conclusions and consensus of opinion are difficult to obtain.

Chapter III of this study detailed the hypotheses to be tested, the methodology to be employed, and the data base used. Chapter IV examined the association of factors considered important in their contribution to earnings with veteran status and race. The general conclusions drawn from this analysis were that black veterans were superior to black non-veterans in earning characteristics, while the reverse was true for whites. These results were consistent with a study conducted by Reaghard (1980). Chapter IV concludes that the military, during the period 1960 to 1976, was not representative of the population from which it was drawn.

In the next chapter multiple regression analysis was used to determine returns to veteran status. It was found that veteran status, regardless of race, had a negative post-service earnings influence of approximately $9 per week, in 1976. For whites that negative influence extended over a period in excess of seven years after the completion of their military

service. These findings were consistent with Cutright (1972) and Bolin et al., (1980). In particular, the results of this thesis, even though cross-sectional for 1976, enhance the Bolin et al., (1980) study which utilized the same NLS data base, but used 1969 and 1971 data. This analysis, combined with the Bolin et al., study, would indicate a longitudinal trend of negative returns to veterans of the Vietnam period. Those veterans who do not improve their education or vocational training during or on completion of military service have poorer earning prospects on their return to the civilian sector, compared to veterans undertaking vocational training or furthering their education.

Of particular interest were the results for black veterans, who though superior in many factors over their non-veteran counterparts, still had an earnings penalty associated with their military service. This result directly conflicts with Martindale et al., (1979). Reasons for this apparent contradiction appear to be the sample selection and the methodology utilized. It was also shown that length of training and length of service in the military were not associated with positive returns. Length of enlistment detracts from the ability to gain civilian job tenure, which had positive returns.

B. CONCLUSIONS

The results of this study would infer that military service is not a good method of investing in human capital. Future earnings are not enhanced by military service. This finding

148

is consistent with Cutright's and Bolin, Hess and Little's
conclusions. This thesis also supports Reaghard's results
that during the 1960's and early 70's better "quality" blacks
were in the military, but "poorer" quality whites entered
military service.

It would seem the "better" whites could generally afford
to avoid the draft, possibly through their easier access to
tertiary education. The "better" blacks, however, who per-
haps could not afford this extra education were drafted or
enlisted in the military. Unfortunately, both the whites and
blacks who join the military for non-careerist reasons would
have been better off economically had they been able to spend
their time gaining work experience or education in the civilian
sector.

In summary, it can be argued that the average veteran
who completed a tour of military in the 1960's and early 1970's
has not benefited financially in his post-service period.
Further, a selective service program that removes members from
the civilian sector and pays a minimal wage during this period
imposes not only a "conscription tax" on those who serve, but
also depresses their earnings in the post-program period.

Additional research is required to determine whether cur-
rent incomes earned during military service have compensated
for losses sustained in the post service environment. This
type of analysis should be possible with the new NLS surveys.
The new NLS, of young men and women aged 14 to 21 in 1979,
surveys not only members currently serving in the military,

but will also survey members during military service should they choose to enlist. With these data it will be possible to compare members of comparative ability before, during, and after military service. Construction of lifetime earning paths that will be possible from these data should be able to assess the cost and benefits of military service under the all volunteer force [Kim, 1980].

Moreover, as the new survey period will cover the era of the All Volunteer Force, interest will also be focused on the "quality" of personnel the services are able to recruit when faced by a competitive labor market. Additional interest in this survey should also come from its ability to answer questions related to military service and women.

C. RECOMMENDATIONS

Policy recommendations determined as a result of this analysis are;

1. Information to employers and formal accreditation of military personnel for both formal and on-the-job training received during military service is urgently required. This certification and recognition of veterans qualifications could ease the veterans transition back into the civilian sector.

2. The government needs to compensate adequately those who serve in the military with either higher wages and/or better post service benefits to reduce financial post service loss. If the implication of being in the Individual Ready Reserve are also considered, it would seem that country is not

only financially disadvantaging non-career veterans but,
in addition, is expecting them as a result of their military
service to be the first to answer the call should the country
go to war.
